## 1 Timeline (in brief)

This is 1.4i of 2021/06/11.

Please refer to [CHANGES.html](#) for a (very) detailed history.

Internet: <http://mirrors.ctan.org/macros/generic/xint/CHANGES.html>

- Release 1.4i of 2021/06/11: extension of the «simultaneous assignments» concept (backwards compatible).
- Release 1.4g of 2021/05/25: powers are now parsed in a right associative way. Removal of the single-character operators &, |, and = (deprecated at 1.1). Reformatted expandable error messages.
- Release 1.4e of 2021/05/05: logarithms and exponentials up to 62 digits, trigonometry still mainly done at high level but with guard digits so all digits up to the last one included can be trusted for faithful rounding and high probability of correct rounding.
- Release 1.4 of 2020/01/31: `xintexpr` overhaul to use `\expanded` based expansion control. Many new features, in particular support for input and output of nested structures. Breaking changes, main ones being the (provisionary) drop of `**[a, b,...]`, `x+[a, b,...]` et al. syntax and the requirement of `\expanded` primitive (currently required only by `xintexpr`).
- Release 1.3e of 2019/04/05: packages `xinttrig`, `xintlog`; `\xintdefefunc` ``non-protected'' variant of `\xintdeffunc` (at 1.4 the two got merged and `\xintdefefunc` became a deprecated alias for `\xintdeffunc`). Indices removed from [sourcexint.pdf](#).
- Release 1.3d of 2019/01/06: fix of 1.2p bug for division with a zero dividend and a one-digit divisor, `\xinteval` et al. wrappers, `gcd()` and `lcm()` work with fractions.
- Release 1.3c of 2018/06/17: documentation better hyperlinked, indices added to [sourcexint.pdf](#). Colon in `:=` now optional for `\xintdefvar` and `\xintdeffunc`.
- Release 1.3b of 2018/05/18: randomness related additions (still WIP).
- Release 1.3a of 2018/03/07: efficiency fix of the mechanism for recursive functions.
- Release 1.3 of 2018/03/01: addition and subtraction use systematically least common multiple of denominators. Extensive under-the-hood refactoring of `\xintNewExpr` and `\xintdeffunc` which now allow recursive definitions. Removal of 1.2o deprecated macros.
- Release 1.2q of 2018/02/06: fix of 1.2l subtraction bug in special situation; tacit multiplication extended to cases such as `10!20!30!`.
- Release 1.2p of 2017/12/05: maps // and /: to the floored, not truncated, division. Simultaneous assignments possible with `\xintdefvar`. Efficiency improvements in `xinttools`.
- Release 1.2o of 2017/08/29: massive deprecations of those macros from `xintcore` and `xint` which filtered their arguments via `\xintNum`.
- Release 1.2n of 2017/08/06: improvements of `xintbinhex`.
- Release 1.2m of 2017/07/31: rewrite of `xintbinhex` in the style of the 1.2 techniques.
- Release 1.2l of 2017/07/26: under the hood efficiency improvements in the style of the 1.2 techniques; subtraction refactored. Compatibility of most `xintfrac` macros with arguments using non-delimited `\the\numexpr` or `\the\mathcode` etc...
- Release 1.2i of 2016/12/13: under the hood efficiency improvements in the style of the 1.2 techniques.

*TOC, xintkernel, xinttools, xintcore, xint, xintbinhex, xintgcd, xintfrac, xintseries, xintcfrac, xintexpr, xinttrig, xintlog*

- Release 1.2 of 2015/10/10: complete refactoring of the core arithmetic macros and faster `\xintexpr` parser.
- Release 1.1 of 2014/10/28: extensive changes in `xintexpr`. Addition and subtraction do not multiply denominators blindly but sometimes produce smaller ones. Also with that release, packages `xintkernel` and `xintcore` got extracted from `xinttools` and `xint`.
- Release 1.09g of 2013/11/22: the `xinttools` package is extracted from `xint`; addition of `\xintloop` and `\xintiloop`.
- Release 1.09c of 2013/10/09: `\xintFor`, `\xintNewNumExpr` (ancestor of `\xintNewExpr`/`\xintdeffunc` mechanism).
- Release 1.09a of 2013/09/24: support for functions by `xintexpr`.
- Release 1.08 of 2013/06/07: the `xintbinhex` package.
- Release 1.07 of 2013/05/25: support for floating point numbers added to `xintfrac` and first release of the `xintexpr` package (provided `\xintexpr` and `\xintfloatexpr`).
- Release 1.04 of 2013/04/25: the `xintcfrac` package.
- Release 1.03 of 2013/04/14: the `xintfrac` and `xintseries` packages.
- Release 1.0 of 2013/03/28: initial release of the `xint` and `xintgcd` packages.

Some parts of the code still date back to the initial release, and at that time I was learning my trade in expandable TeX macro programming. At some point in the future, I will have to re-examine the older parts of the code.

Warning: pay attention when looking at the code to the catcode configuration as found in `\XINT_setcatcodes`. Additional temporary configuration is used at some locations. For example `!` is of catcode letter in `xintexpr` and there are locations with funny catcodes e.g. using some letters with the math shift catcode.

## 2 Package [xintkernel](#) implementation

.1	Catcodes, $\varepsilon$ - $\text{\TeX}$ and reload detection . . . . .	4	.12	$\backslash$ xintReverseOrder . . . . .	11
.1.1	$\backslash$ XINTrestorecatcodes, $\backslash$ XINTsetcatcodes, $\backslash$ XINTrestorecatcodesendinput . . . . .	5	.13	$\backslash$ xintLength . . . . .	11
.2	Package identification . . . . .	7	.14	$\backslash$ xintLastItem . . . . .	12
.3	Constants . . . . .	7	.15	$\backslash$ xintFirstItem . . . . .	12
.4	(WIP) $\backslash$ xint_texuniformdeviate and needed counts . . . . .	8	.16	$\backslash$ xintLastOne . . . . .	13
.5	Token management utilities . . . . .	8	.17	$\backslash$ xintFirstOne . . . . .	13
.6	"gob til" macros and UD style fork . . . . .	9	.18	$\backslash$ xintLengthUpTo . . . . .	14
.7	$\backslash$ xint_afterfi . . . . .	9	.19	$\backslash$ xintreplicate, $\backslash$ xintReplicate . . . . .	14
.8	$\backslash$ xint_bye, $\backslash$ xint_Bye . . . . .	9	.20	$\backslash$ xintgobble, $\backslash$ xintGobble . . . . .	16
.9	$\backslash$ xintdothis, $\backslash$ xintorthat . . . . .	10	.21	(WIP) $\backslash$ xintUniformDeviate . . . . .	18
.10	$\backslash$ xint_zapspaces . . . . .	10	.22	$\backslash$ xintMessage, $\backslash$ ifxintverbose . . . . .	19
.11	$\backslash$ odef, $\backslash$ oodef, $\backslash$ fdef . . . . .	10	.23	$\backslash$ ifxintglobaldefs, $\backslash$ XINT_global . . . . .	19
			.24	(WIP) Expandable error message . . . . .	19

This package provides the common minimal code base for loading management and catcode control and also a few programming utilities. With 1.2 a few more helper macros and all  $\backslash$ chardef's have been moved here. The package is loaded by both [xintcore.sty](#) and [xinttools.sty](#) hence by all other packages.

1.1 (2014/10/28). Separated package.

1.2i (2016/12/13).  $\backslash$ xintreplicate,  $\backslash$ xintgobble,  $\backslash$ xintLengthUpTo and  $\backslash$ xintLastItem, and faster  $\backslash$ xintLength.

1.3b (2018/05/18).  $\backslash$ xintUniformDeviate.

1.4 (2020/01/31) [commented 2020/01/11].  $\backslash$ xintReplicate,  $\backslash$ xintGobble,  $\backslash$ xintLastOne,  $\backslash$ xintFirstOne.

### 2.1 Catcodes, $\varepsilon$ - $\text{\TeX}$ and reload detection

The code for reload detection was initially copied from **HEIKO OBERDIEK**'s packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

125 }%

```

## 2.2 Package identification

Inspired from HEIKO OBERDIEK's packages. Modified in 1.09b to allow re-use in the other modules. Also I assume now that if `\ProvidesPackage` exists it then does define `\ver@<pkgnname>.sty`, code of HO for some reason escaping me (compatibility with LaTeX 2.09 or other things ??) seems to set extra precautions.

```

1.09c uses e-TeX \ifdefined.

126 \ifdefined\ProvidesPackage
127   \let\XINT_providespackage\relax

```

## 2.5 Token management utilities

**1.3b (2018/05/18).** `\xint_gobandstop...` macros because this is handy for `\xintRandomDigits. 1.3b` forces `\empty` and `\space` to have their standard meanings, rather than simply alerting user in the (theoretical) case they don't that nothing will work. If some L<sup>A</sup>T<sub>E</sub>X user has `\renewcommanded` them they will be long and this will trigger xint redefinitions and warnings.

```

## 2.7 \xint\_afterfi

```
243 \long\def\xint_afterfi #1#2\fi {\fi #1}%
```

## 2.8 \xint\_bye, \xint\_Bye

1.09 (2013/09/23). [\xint\\_bye](#)

1.2i (2016/12/13). [\xint\\_Bye](#) for [\xintDSRr](#) and [\xintRound](#). Also [\xint\\_stop\\_afterbye](#).

```
244 \long\def\xint_bye #1\xint_bye { }%
```

```
245 \long\def\xint_Bye #1\xint_bye {}%
246 \long\def\xint_stop_afterbye #1\xint_bye { }%
```

## 2.9 \xintdothis, \xintorthat

1.1 (2014/10/28).

1.2 (2015/10/10). Names without underscores.

To be used this way:

```
\if..\xint_dothis{..}\fi
\if..\xint_dothis{..}\fi
\if..\xint_dothis{..}\fi
...more such...
\xint_orthat{...}
```

Ancient testing indicated it is more efficient to list first the more improbable clauses.

```
247 \long\def\xint_dothis #1#2\xint_orthat #3{\fi #1}% 1.1
248 \let\xint_orthat \xint_firstofone
249 \long\def\xintdothis #1#2\xintorthat #3{\fi #1}%
250 \let\xintorthat \xint_firstofone
```

## 2.10 \xint\_zapspaces

1.1 (2014/10/28).

This little (quite fragile in the normal sense i.e. non robust in the normal sense of programming lingua) utility zaps leading, intermediate, trailing, spaces in completely expanding context ([\e](#) def, [\csname...](#)[\endcsname](#)).

Usage: `\xint_zapspaces foo<space>\xint_gobble_i`

Explanation: if there are leading spaces, then the first #1 will be empty, and the first #2 being undelimited will be stripped from all the remaining leading spaces, if there was more than one to start with. Of course brace-stripping may occur. And this iterates: each time a #2 is removed, either we then have spaces and next #1 will be empty, or we have no spaces and #1 will end at the first space. Ultimately #2 will be `\xint_gobble_i`.

The `\zap@spaces` of LaTeX2e handles unexpectedly things such as

```
\zap@spaces 1 {22} 3 4 \@empty
```

(spaces are not all removed). This does not happen with `\xint_zapspaces`.

But for example `\foo{aa} {bb} {cc}` where `\foo` is a macro with three non-delimited arguments breaks expansion, as expansion of `\foo` will happen with `\xint_zapspaces` still around, and even if it wasn't it would have stripped the braces around `{bb}`, certainly breaking other things.

Despite such obvious shortcomings it is enough for our purposes. It is currently used by `xintexpr` at various locations e.g. cleaning up optional argument of `\xintiexpr` and `\xintfloatexpr`; maybe in future internal usage will drop this in favour of a more robust utility.

1.2e (2015/11/22). `\xint_zapspaces_o`.

1.2i (2016/12/13). Made `\long`.

ATTENTION THAT `xinttools` HAS AN `\xintzapspaces` WHICH SHOULD NOT GET CONFUSED WITH THIS ONE.

```
251 \long\def\xint_zapspaces #1 #2{\#1#2\xint_zapspaces }% 1.1
252 \long\def\xint_zapspaces_o #1{\expandafter\xint_zapspaces#1 \xint_gobble_i}%
```

## 2.11 \odef, \oodef, \fdef

May be prefixed with `\global`. No parameter text.

```
253 \def\xintodef #1{\expandafter\def\expandafter#1\expandafter }%
254 \def\xintoodef #1{\expandafter\expandafter\expandafter\def }

261 \ifdefined\fdef\else\let\fdef\xintfdef\fi

```

## 2.12 \xintReverseOrder

**1.0 (2013/03/28).** Does not expand its argument. The whole of `xint` codebase now contains only two calls to `\XINT_rord_main` (in `xintgcd`).

Attention: removes brace pairs (and swallows spaces).

For digit tokens a faster reverse macro is provided by (1.2) `\xintReverseDigits` in `xint`.

For comma separated items, 1.2g has `\xintCSVReverse` in `xinttools`.

```

262 \def\xintReverseOrder {\romannumeral0\xintreverseorder }%
263 \long\def\xintreverseorder #1%
264 {%
265   \XINT_rord_main {}#1%
266   \xint:
267     \xint_bye\xint_bye\xint_bye\xint_bye

278 {%
279   \expandafter#1\xint_gob_til_xint: ##1%
280 }}\XINT_rord_cleanup { }%

```

## 2.13 \xintLength

**1.0 (2013/03/28).** Does not expand its argument. See `\xintNthElt{0}` from `xinttools` which f-expands its argument.

**1.2g (2016/03/19).** Added `\xintCSVLength` to `xinttools`.

**1.2i (2016/12/13).** Rewrote this venerable macro. New code about 40% faster across all lengths.

Syntax with `\romannumeral0` adds some slight (negligible) overhead; it is done to fit some general principles of structure of the `xint` package macros but maybe at some point I should drop it.

And in fact it is often called directly via the `\numexpr` access point. (bad coding...)

```

281 \def\xintLength {\romannumeral0\xintlength }%
282 \def\xintlength #1{%
283 \long\def\xintlength ##1%

327 \def\xINT_firstitem_end\xint:{ }%

```

## 2.16 \xintLastOne

As `xintexpr` 1.4 uses `{c1}{c2}....{cN}` storage when gathering comma separated values we need to not handle identically an empty list and a list with an empty item (as the above allows hierarchical structures). But `\xintLastItem` removed one level of brace pair so it is inadequate for the `last()` function.

By the way it is logical to interpret «item» as meaning `{cj}` inclusive of the braces; but legacy `xint` user manual was not written in this spirit. And thus `\xintLastItem` did brace stripping, thus we need another name for maintaining backwards compatibility (although the cardinality of users is small).

The `\xint:` token must not be found (visible) among the item contents.

```

328 \def\xintLastOne {\romannumeral0\xintlastone }%

```

## 2.17 \xintFirstOne

For `xintexpr` 1.4 too. Jan 3, 2020.

This is an experimental macro, don't use it. If input is nil (empty set) it expands to nil, if not it fetches first item and braces it. Fetching will have stripped one brace pair if item was braced to start with, which is the case in non-symbolic `xintexpr` data objects.

I have not given much thought to this (make it shorter, allow all tokens, (we could first test if empty via combination with `\detokenize`), etc...) as I need to get `xint` 1.4 out soon. So in particular attention that the macro assumes the `\xint:` token is absent from first item of input.

```

351 \def\xintFirstOne {\romannumeral0\xintfirstone }%
352 \long\def\xintfirstone #1{\XINT_firstone #1{\xint:\XINT_firstone_empty}\xint:}%

354 \def\XINT_firstone_empty\xint:#1{ }%

```

## 2.18 \xintLengthUpTo

**1.2i (2016/12/13).** For use by `\xintKeep` and `\xintTrim` (`xinttools`). The argument `N` \*\*must be non-negative\*\*.

`\xintLengthUpTo{N}{List}` produces `-0` if `length(List)>N`, else it returns `N-length(List)`. Hence subtracting it from `N` always computes `min(N,length(List))`.

**1.2j (2016/12/22).** Changed ending and interface to core loop.

```
355 \def\xintLengthUpTo {\romannumeral0\xintlengthupto}%

## 2.19 \xintreplicate, \xintReplicate

**1.2i (2016/12/13).**

This is cloned from LaTeX3's `\prg_replicate:nn`, see Joseph's post at

<http://tex.stackexchange.com/questions/16189/repeat-command-n-times>

I posted there an alternative not using the chained `\csname`'s but it is a bit less efficient (except perhaps for thousands of repetitions). The code in Joseph's post does `abs(#1)` replications when input `#1` is negative and then activates an error triggering macro; here we simply do nothing when `#1` is negative.

Usage: `\romannumeral\xintreplicate{N}{stuff}`

When  $N$  is already explicit digits (even  $N=0$ , but non-negative) one can call the macro as  
 $\text{\romannumeral}\text{\XINT\_rep } N\text{\endcsname }\{foo\}$

to skip the  $\text{\numexpr}$ .

**1.4 (2020/01/31) [commented 2020/01/11].** Added  $\text{\xintReplicate}$  ! The reason I did not before is that the prevailing habits in xint source code was to trigger with  $\text{\romannumeral}0$  not  $\text{\romannumeral}$  which is the lowercased named macros. Thus adding the camelcase one creates a couple  $\text{\xintReplicate}/\text{\xintreplicate}$  not obeying the general mold.

```

## 2.20 `\xintgobble`, `\xintGobble`

1.2i (2016/12/13).

I hesitated about allowing as many as  $9^{6-1}=531440$  tokens to gobble, but  $9^{5-1}=59058$  is too low for playing with long decimal expansions.

Usage: `\romannumeral\xintgobble{N}...`

1.4 (2020/01/31) [commented 2020/01/11]. Added `\xintGobble`.

```

588   \newlinechar\XINT_newlinechar\space
589 }%
590 \newif\ifxintverbose

```

## 2.23 \ifxintglobaldefs, \XINT\_global

**1.3c** (2018/06/17).

```

591 \newif\ifxintglobaldefs
592 \def\XINT_global{\ifxintglobaldefs\global\fi}%

```

## 2.24 (WIP) Expandable error message

**1.21** (2017/07/26) [commented 2017/07/26]. But really belongs to next major release beyond [1.3](#). Basically copied over from l3kernel code. Using `\ ! /` control sequence, which must be left undefined. `\xintError:` would be 6 letters more.

**1.4** (2020/01/31) [commented 2020/01/25]. Finally rather than `\ ! /` I use `\xint/`.

**1.4g** (2021/05/25) [commented 2021/05/19]. Rewrote to use not an undefined control sequence but trigger "Use of `\xint/` doesn't match its definition." message.

**1.4g** (2021/05/25) [commented 2021/05/20]. Things evolve fast and I switch to a third method which will exploit "Paragraph ended before `\foo` was complete" style error. See

<https://github.com/latex3/latex3/issues/931#issuecomment-845367201>

However I can not fully exploit this because `xint` may be used with Plain etex which does not set `\newlinechar`. I can only use a poorman version with no usage of `^J`. Also `xintsession` could use the `^J`, maybe I will integrate it there.

I. Explanations on 2021/05/19 and 2021/05/20 before final change

First I tried out things with undefined control sequence such as

`\ ! an error was reported by xint ...`

whose output produces a nice symmetrical display with no `\`, and with `...` both on left and right but this reduces drastically the available space for the actual error context. No go. But see 2021/05/20 update below!

Having replaced `\xint/` by "`\xint` ", I next opted provisionally for "`\Hit RET at ?`" control sequence, despite it being quite longer. And then I thought about using "`\ xint error`", possibly with an included `^J` in the name, or in the context.

I experimented with `^^J` in the context. But the context size is much constrained, and when `\errorcontextlines` is at its default value of 5 for etex, not -1 as done by LaTeX, having the info shifted to the right makes it actually more visible. (however I have now updated `xintsession` to 0.2b which sets `\errorcontextlines` to 0)

So I was finally back here to square one, apart from having replaced "`\xint/`" by the more longish "`\xint error`", hesitating with "`\xintinterrupt`"...

Then I had the idea to replace the undefined control sequence method by a method with a macro `\foo` defined as `\def\foo.{}{}` but used as `\foo<space>` for example. This gives something like this (the first line will be otherwise if engine is run with `-file-line-error`):

! Use of `\xint/` doesn't match its definition.

`<argument> \xint/`

Ooops, looks like we are missing a ] (hit RET)

`\xint/<space>` (where the space is the unexpected token, the definition expecting rather a full stop) makes for 7 characters to compare to `\xint error` which had 12, so I gained back 5.

Back to `^^J`: I had overlooked that TeX in the first part of the error message will display `\macro` fully, so inserting `^^J` in its name allows arbitrarily long expandable error messages... as pointed out by BLF in `latex3/issues#931` as I read on the morning of 2021/05/20. This is very nice but requires to predefine control sequences for each message, and also the actual arguments #1, #2, ... values can appear only in the context.

And the situation with `^^J` is somewhat complicated:

`xintsession` sets the `\newlinechar` to 10, but this is not the case with bare usage of `xintexpr` with etex. And this matters. To discuss `^^J` we have to separate two locations:

- it appears in the control sequence name,
- or in the context (which itself has two parts)

1) When in the context, what happens with `^^J` is independent of the setting of `\newlinechar`: and with TeXLive pdflatex the `^^J` will induce a linebreak, but with xelatex it must be used with option `-8bit`.

2) When in the control sequence name the behaviour in log/terminal of `^^J` is influenced by the setting of `\newlinechar`. Although with pdflatex it will always induce a linebreak, the actual count of characters where TeX will forcefully break is influenced by whether `^^J` is or not `\newlinechar`. And with xelatex if it is `\newlinechar`, it does not depend then if `-8bit` or not, but if not `\newlinechar` then it does and TeX forceful breaks also change as for pdflatex.

So, the control sequence name trick can be used to obtain arbitrarily long messages, but the `\newlinechar` must be set.

And in the context, we can try to insert some `^^J` but this would need with xetex the `-8bit` option, and anyhow the context size is limited, and there is apparently no trick to get it larger.

So, in view of all the above I decided not to use `^^J` (rather `&&J` here) at all, whether here in the control sequence or the context or inserted in `\XINT_signalcondition` in the context!

I also have a problem with usage from `bnumexpr` or `polexpr` for example, they would need their own to avoid perhaps displaying `\xint/` or analogous.

II. Finally I modified again the method (completely, and no more need for funny catcode 7 space as delimiter) as this allows a longer context message, starting at start of line, and which obeys `^^J` if `\newlinechar` is set to it. It also allows to incorporate non-limited generic explanations as a postfix, with linebreaks if `\newlinechar` is known.

But as `xintexpr` can be used with Plain+etex which does not set the `\newlinechar`, I can't use `^^J` out of the box. I can in `xintsession`. What I decided finally is to make a conditional definition here.

In both cases I include the "hit RET" (how rather "hit <return>") in the control sequence name serving to both provide extra information and trigger the error from being defined short and finding a `\par`.

The maximal size was increased from 48 characters (method with `\xint/` being badly delimited), to now 55 characters (using "`! xint error:<^^J or space>`" as prefix to the message). Longer messages

are truncated at 56 characters with an appended "\ETC.".

As it is late on this 2021/05/20, and in order to not have to change all usages, I keep `\XINT_signalcondition` (in `xintcore`) as a one argument macro for time being, so will not include a more specific module name.

The `\par` token has a special role here, and can't be (I)nserted without damage, but who would want to insert it in an expandable computation anyhow... and I don't need it in my custom error messages for sure.

On 2021/05/21 I add a test about `\newlinechar` at time of package loading, and make two distinct definitions: one using `^^J` in the control sequence, the other not using it.

The -file-line-error toggle makes it impossible to control if the line-break on first line will match next lines. In the `^^J` branch I insert "`|` " (no, finally " `"`  with two spaces) at start of continuation lines. Also I preferred to ensure a good-looking first line break for the case it starts with a "`!` Paragraph ended ..." because a priori error messages will be read if -file-line-error was emitted only a fortiori (this toggle suggests some IDE launched TeX and probably `-interaction=nonstopmode`).

I will perhaps make another definition in `xintsession` (it currently loads `xintexpr` prior to having set the `\newlinechar`, so the no `^^J` definition will be used, if nothing else is modified there).

With some hesitation I do not insert a `^^J` after "`! xint error:`", as Emacs/AucTeX will display only the first line prominently and then the rest (which is in file:line:error mode) in one block under "`--- TeX said ---`". I use the `^^J` only in the generic helper message embedded in the control sequence. The cases with or without `\newlinechar` being 10 diverge a bit, as in the latter case I had to ensure acceptable linebreaks at 79 chars, and I did that first and then had spent enough time on the matter not to add more to backport the latest `^^J` style message.

Release 1.09g of 2013/11/22 splits off *xinttools.sty* from *xint.sty*. Starting with 1.1, *xinttools* ceases being loaded automatically by *xint*.

#### 3.1 Catcodes, $\varepsilon$ - $\text{\TeX}$ and reload detection

The code for reload detection was initially copied from HEIKO OBERDIEK's packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

```

1 \begingroup\catcode61\catcode48\catcode32=10\relax%
2 \catcode13=5 % ^^M
3 \endlinechar=13 %
4 \catcode123=1 % {
5 \catcode125=2 % }
6 \catcode64=11 % @
7 \catcode35=6 % #
8 \catcode44=12 % ,
9 \catcode45=12 % -
10 \catcode46=12 % .
11 \catcode58=12 % :
12 \let\z\endgroup
13 \expandafter\let\expandafter\x\csname ver@xinttools.sty\endcsname
14 \expandafter\let\expandafter\w\csname ver@xintkernel.sty\endcsname
15 \expandafter

```

```

16   \ifx\csname PackageInfo\endcsname\relax
17     \def\y#1#2{\immediate\write-1{Package #1 Info: #2.}}%
18   \else
19     \def\y#1#2{\PackageInfo{#1}{#2}}%

### 3.2 Package identification

```

44 \XINT_providespackage
45 \ProvidesPackage{xinttools}%
46 [2021/06/11 v1.4i Expandable and non-expandable utilities (JFB)]%
  

  \XINT_toks is used in macros such as \xintFor. It is not used elsewhere in the xint bundle.
47 \newtoks\XINT_toks
48 \xint_firstofone{\let\XINT_sptoken= } %- space here!

```

### 3.3 \xintgodef, \xintgoodef, \xintgfdef

1.09i. For use in \xintAssign.

```

49 \def\xintgodef {\global\xintodef }%
50 \def\xintgoodef {\global\xintoodef }%
51 \def\xintgfdef {\global\xintfdef }%

```

### 3.4 \xintRevWithBraces

New with 1.06. Makes the expansion of its argument and then reverses the resulting tokens or braced tokens, adding a pair of braces to each (thus, maintaining it when it was already there.) The reason for \xint:, here and in other locations, is in case #1 expands to nothing, the \romannumeral-`0 must be stopped

```

52 \def\xintRevWithBraces          {\romannumeral0\xintrevwithbraces }%

89 }\XINT_revwbr_finish_c{ }%

```

### 3.5 \xintZapFirstSpaces

1.09f, written [2013/11/01]. Modified (2014/10/21) for release 1.1 to correct the bug in case of an empty argument, or argument containing only spaces, which had been forgotten in first version. New version is simpler than the initial one. This macro does NOT expand its argument.

```

90 \def\xintZapFirstSpaces {\romannumeral0\xintzapfirstspaces }%
91 \def\xintzapfirstspaces#1{\long
92 \def\xintzapfirstspaces ##1{\XINT_zapbsp_a #1##1\xint:#1#1\xint:}%
93 }\xintzapfirstspaces{ }%

```

If the original #1 started with a space, the grabbed #1 is empty. Thus \_again? will see #1=\xint\_bye, and hand over control to \_again which will loop back into \XINT\_zapbsp\_a, with one

initial space less. If the original #1 did not start with a space, or was empty, then the #1 below will be a <sptoken>, then an extract of the original #1, not empty and not starting with a space, which contains what was up to the first <sp><sp> present in original #1, or, if none preexisted, <sptoken> and all of #1 (possibly empty) plus an ending \xint:. The added initial space will stop later the \romannumeral0. No brace stripping is possible. Control is handed over to \XINT\_zapbsp\_b which strips out the ending \xint:<sp><sp>\xint:

```
94 \def\XINT_zapbsp_a#1{\long\def\XINT_zapbsp_a ##1#1#1{%
95   \XINT_zapbsp_again?##1\xint_bye\XINT_zapbsp_b ##1#1#1}%
96 }\XINT_zapbsp_a{ }%
97 \long\def\XINT_zapbsp_again? #1{\xint_bye #1\XINT_zapbsp_again }%
98 \xint_firstofone{\def\XINT_zapbsp_again\XINT_zapbsp_b} {\XINT_zapbsp_a }%
99 \long\def\XINT_zapbsp_b #1\xint:#2\xint:{#1}%
```

### 3.6 \xintZapLastSpaces

[1.09f](#), written [2013/11/01].

```
100 \def\xintZapLastSpaces {\romannumeral0\xintzaplastspaces }%
101 \def\xintzaplastspaces#1{\long
102 \def\xintzaplastspaces ##1{\XINT_zapesp_a {}{\empty##1#1}\xint_bye\xint:{}}%
103 }\xintzaplastspaces{ }%
```

The \empty from \xintzaplastspaces is to prevent brace removal in the #2 below. The \expandafter chain removes it.

```
104 \xint_firstofone {\long\def\XINT_zapesp_a #1#2 } %<- second space here
105   {\expandafter\XINT_zapesp_b\expandafter{#2}{#1}}%
```

Notice again an \empty added here. This is in preparation for possibly looping back to \XINT\_zapesp\_a. If the initial #1 had no <sp><sp>, the stuff however will not loop, because #3 will already be <some spaces>\xint\_bye. Notice that this macro fetches all way to the ending \xint:. This looks not very efficient, but how often do we have to strip ending spaces from something which also has inner stretches of \_multiple\_ space tokens ?;-).

```
106 \long\def\XINT_zapesp_b #1#2#3\xint:%
107   {\XINT_zapesp_end? #3\XINT_zapesp_e {#2#1}\empty #3\xint:{}}%
```

When we have been over all possible <sp><sp> things, we reach the ending space tokens, and #3 will be a bunch of spaces (possibly none) followed by \xint\_bye. So the #1 in \_end? will be \xint\_bye. In all other cases #1 can not be \xint\_bye (assuming naturally this token does nor arise in original input), hence control falls back to \XINT\_zapesp\_e which will loop back to \XINT\_zapesp\_a.

```
108 \long\def\XINT_zapesp_end? #1{\xint_bye #1\XINT_zapesp_end }%
```

We are done. The #1 here has accumulated all the previous material, and is stripped of its ending spaces, if any.

```
109 \long\def\XINT_zapesp_end\XINT_zapesp_e #1#2\xint:{ #1}%
```

We haven't yet reached the end, so we need to re-inject two space tokens after what we have gotten so far. Then we loop.

```
110 \def\XINT_zapesp_e#1{%
111 \long\def\XINT_zapesp_e ##1{\XINT_zapesp_a {##1#1#1}}%
112 }\XINT_zapesp_e{ }%
```

### 3.7 \xintZapSpaces

1.09f, written [2013/11/01]. Modified for 1.1, 2014/10/21 as it has the same bug as \xintZapFirstSpaces. We in effect do first \xintZapFirstSpaces, then \xintZapLastSpaces.

```
113 \def\xintZapSpaces {\romannumeral0\xintzapspaces }%
114 \def\xintzapspaces#1{%
115 \long\def\xintzapspaces ##1 like \xintZapFirstSpaces.
116     {\XINT_zapsp_a #1##1\xint:#1#1\xint:}%
117 }\xintzapspaces{ }%
118 \def\XINT_zapsp_a#1{%
119 \long\def\XINT_zapsp_a ##1#1#1%
120     {\XINT_zapsp_again?##1\xint_bye\XINT_zapsp_b##1#1#1}%
121 }\XINT_zapsp_a{ }%
122 \long\def\XINT_zapsp_again? #1{\xint_bye #1\XINT_zapsp_again }%
123 \xint_firstofone{\def\XINT_zapsp_again\XINT_zapsp_b} {\XINT_zapsp_a }%
124 \xint_firstofone{\def\XINT_zapsp_b} {\XINT_zapsp_c }%
125 \def\XINT_zapsp_c#1{%
126 \long\def\XINT_zapsp_c ##1\xint:##2\xint:%
127     {\XINT_zapesp_a{} }\empty ##1#1#\xint_bye\xint:}%
128 }\XINT_zapsp_c{ }%
```

### 3.8 \xintZapSpacesB

1.09f, written [2013/11/01]. Strips up to one pair of braces (but then does not strip spaces inside).

```
129 \def\xintZapSpacesB {\romannumeral0\xintzapspacebs }%
130 \long\def\xintzapspacebs #1{\XINT_zapspb_one? #1\xint:\xint:%
131             \xint_bye\xintzapspaces {#1}}%
132 \long\def\XINT_zapspb_one? #1#2%
133     {\xint_gob_til_xint: #1\XINT_zapspb_onlyspaces\xint:%
134     \xint_gob_til_xint: #2\XINT_zapspb_bracedorone\xint:%
135     \xint_bye {#1}}%
136 \def\XINT_zapspb_onlyspaces\xint:%
137     \xint_gob_til_xint:\xint:\XINT_zapspb_bracedorone\xint:%
138     \xint_bye #1\xint_bye\xintzapspaces #2{ }%
139 \long\def\XINT_zapspb_bracedorone\xint:%
140     \xint_bye #1\xint:\xint_bye\xintzapspaces #2{ #1}%

```

### 3.9 \xintCSVtoList, \xintCSVtoListNonStripped

\xintCSVtoList transforms a,b,...,z into {a}{b}...{z}. The comma separated list may be a macro which is first f-expanded. First included in release 1.06. Here, use of \Z (and \R) perfectly safe.

[2013/11/02]: Starting with 1.09f, automatically filters items with \xintZapSpacesB to strip away all spaces around commas, and spaces at the start and end of the list. The original is kept as \xintCSVtoListNonStripped, and is faster. But ... it doesn't strip spaces.

ATTENTION: if the input is empty the output contains one item (empty, of course). This means an \xintFor loop always executes at least once the iteration, contrarily to \xintFor\*.

```
141 \def\xintCSVtoList {\romannumeral0\xintcsvtolist }%
142 \long\def\xintcsvtolist #1{\expandafter\xintApply
143     \expandafter\xintzapspacesb
144     \expandafter{\romannumeral0\xintcsvtolistnonstripped{#1}}}%
```

```

### 3.10 \xintListWithSep

1.04. `\xintListWithSep {\sep}{{a}{b}...{z}}` returns a `\sep b \sep ....\sep z`. It f-expands its second argument. The 'sep' may be `\par`'s: the macro `\xintlistwithsep` etc... are all declared long. 'sep' does not have to be a single token. It is not expanded. The "list" argument may be empty.

`\xintListWithSepNoExpand` does not f-expand its second argument.

This venerable macro from 1.04 remained unchanged for a long time and was finally refactored at 1.2p for increased speed. Tests done with a list of identical `\x` items and a sep of `\z` demonstrated a speed increase of about:

- 3x for 30 items,
- 4.5x for 100 items,
- 7.5x--8x for 1000 items.

```

### 3.11 \xintNthElt

First included in release 1.06. Last refactored in 1.2j.

`\xintNthElt {i}{List}` returns the *i* th item from List (one pair of braces removed). The list is first f-expanded. The `\xintNthEltNoExpand` does no expansion of its second argument. Both variants expand *i* inside `\numexpr`.

With *i* = 0, the number of items is returned using `\xintLength` but with the List argument f-expanded first.

Negative values return the  $|i|$ th element from the end.

When *i* is out of range, an empty value is returned.

```

### 3.13 \xintKeep

First included in release 1.09m.

\xintKeep{i}{L} f-expands its second argument L. It then grabs the first i items from L and discards the rest.

ATTENTION: \*\*each such kept item is returned inside a brace pair\*\* Use \xintKeepUnbraced to avoid that.

For i equal or larger to the number N of items in (expanded) L, the full L is returned (with braced items). For i=0, the macro returns an empty output. For i<0, the macro discards the first N-|i| items. No brace pairs added to the remaining items. For i is less or equal to -N, the full L is returned (with no braces added.)

\xintKeepNoExpand does not expand the L argument.

Prior to 1.2i the code proceeded along a loop with no pre-computation of the length of L, for the i>0 case. The faster 1.2i version takes advantage of novel \xintLengthUpTo from xintkernel.sty.

```

### 3.14 \xintKeepUnbraced

1.2a. Same as `\xintKeep` but will \*not\* add (or maintain) brace pairs around the kept items when  $\text{length}(L)>i>0$ .

The name may cause a mis-understanding: for  $i<0$ , (i.e. keeping only trailing items), there is no brace removal at all happening.

*Modified for 1.2i like `\xintKeep`.*

### 3.15 \xintTrim

First included in release 1.09m.

\xintTrim{i}{L} f-expands its second argument L. It then removes the first i items from L and keeps the rest. For i equal or larger to the number N of items in (expanded) L, the macro returns an empty output. For i=0, the original (expanded) L is returned. For i<0, the macro proceeds from the tail. It thus removes the last |i| items, i.e. it keeps the first N-|i| items. For |i|>= N, the empty list is returned.

\xintTrimNoExpand does not expand the L argument.

Speed improvements with 1.2i for  $i < 0$  branch (which hands over to `\xintKeep`). Speed improvements with 1.2j for  $i > 0$  branch which gobbles items nine by nine despite not knowing in advance if it will go too far.

```

### 3.17 \xintApply

```
\xintApply {\macro}{\{a\}\{b\}...{\z}} returns {\macro{a}}...{\macro{b}} where each instance of \macro is f-expanded. The list itself is first f-expanded and may thus be a macro. Introduced with release 1.04.

### 3.18 \xintApply:x (WIP, commented-out)

Done for 1.4 (2020/01/27). For usage in the NumPy-like slicing routines. Well, actually, in the end I stucked with old-fashioned (quadratic cost) \xintApply for 1.4 2020/01/31 release. See comments there.

(Comments mainly from 2020/01/27, but on 2020/02/24 I comment out the code and add an alternative)

To expand in \expanded context, and does not need to do any expansion of its second argument.

This uses techniques I had developed for 1.2i/1.2j Keep, Trim, Length, LastItem like macros, and I should revamp venerable \xintApply probably too. But the latter f-expandability (if it does not have \expanded at disposal) complicates significantly matters as it has to store material and release at very end.

Here it is simpler and I am doing it quickly as I really want to release 1.4. The \xint: token should not be located in looped over items. I could use something more exotic like the null char with catcode 3...

```

}%
}
```

### 3.19 \xintApplyUnbraced

`\xintApplyUnbraced {\macro}{a}{b}...{z}` returns `\macro{a}... \macro{z}` where each instance of `\macro` is f-expanded using `\romannumeral-`0`. The second argument may be a macro as it is itself also f-expanded. No braces are added: this allows for example a non-expandable `\def` in `\macro`, without having to do `\gdef`. Introduced with release 1.06b.

```

```

### 3.20 \xintApplyUnbraced:x (WIP, commented-out)

Done for 1.4, 2020/01/27. For usage in the NumPy-like slicing routines.

The items should not contain \xint: and the applied macro should not contain \empty.

Finally, `xintexpr.sty` 1.4 code did not use this macro but the f-expandable one `\xintApplyUnbraced`.

For 1.4b I prefer leave the code commented out, and classify it as WIP.

### 3.21 \xintZip (WIP, not public)

1.4b. (2020/02/25)

Support for `zip()`. Requires `\expanded`.

The implementation here thus considers the argument is already completely expanded and is a sequence of nut-ples. I will come back at later date for more generic macros.

Consider even the name of the function `zip()` as WIP.

As per what this does, it imitates the `zip()` function. See [xint-manual.pdf](#).

I use lame terminators. Will think again later on this. I have to be careful with the used terminators, in particular with the NE context in mind.

Generally speaking I will think another day about efficiency else I will never start this.

OK, done. More compact than I initially thought. Various things should be commented upon here.

Well, actually not so compact in the end as I basically had to double the whole thing simply to avoid the overhead of having to grab the final result delimited by some `\xint_bye\xint_bye\xint_bye\xint_bye\empty` terminator. Now actually rather `\xint_bye\xint_bye\xint_bye\xint_bye\xint`:

```

573 \def\xintZip #1{\expanded\xINT_zip_A#1\xint_bye\xint_bye}%
574 \def\xINT_zip_A#1%
575 {%
576     \xint_bye#1{\expandafter}\xint_bye
577     \expanded{\unexpanded{\XINT_ziptwo_A
578         #1\xint_bye\xint_bye\xint_bye\xint_bye\xint:}}\expandafter}%
579     \expanded\xINT_zip_a
580 }%
581 \def\xINT_zip_a#1%
582 {%
583     \xint_bye#1\xINT_zip_terminator\xint_bye
584     \expanded{\unexpanded{\XINT_ziptwo_a
585         #1\xint_bye\xint_bye\xint_bye\xint_bye\xint:}}\expandafter}%
586     \expanded\xINT_zip_a
587 }%
588 \def\xINT_zip_terminator\xint_bye#1\xint_bye{{}\empty\empty\empty\xint:}%

```

```

589 \def\XINT_ziptwo_a #1#2#3#4#5\xint:#6#7#8#9%
590 {%
591     \bgroup
592     \xint_bye #1\XINT_ziptwo_e \xint_bye
593     \xint_bye #6\XINT_ziptwo_e \xint_bye {{#1}#6}%
594     \xint_bye #2\XINT_ziptwo_e \xint_bye
595     \xint_bye #7\XINT_ziptwo_e \xint_bye {{#2}#7}%
596     \xint_bye #3\XINT_ziptwo_e \xint_bye
597     \xint_bye #8\XINT_ziptwo_e \xint_bye {{#3}#8}%
598     \xint_bye #4\XINT_ziptwo_e \xint_bye
599     \xint_bye #9\XINT_ziptwo_e \xint_bye {{#4}#9}%

```

Attention here that #6 can very well deliver no tokens at all. But the \ifx will then do the expected thing. Only mentioning!

By the way, the \xint\_bye method means TeX needs to look into tokens but skipping braced groups. A conditional based method lets TeX look only at the start but then it has to find \else or \fi so here also it must looks at tokens, and actually goes into braced groups. But (written 2020/02/26) I never did serious testing comparing the two, and in xint I have usually preferred \xint\_bye/\xint\_gob\_til\_foo types of methods (they proved superior than \ifnum to check for 0000 in numerical core context for example, at the early days when xint used blocks of 4 digits, not 8), or usage of \if/\ifx only on single tokens, combined with some \xint\_dothis/\xint\_orthat syntax.

```

### 3.26 \xintApplyInline

1.09a: `\xintApplyInline\macro{{a}{b}...{z}}` has the same effect as executing `\macro{a}` and then applying again `\xintApplyInline` to the shortened list `{b}...{z}` until nothing is left. This is a non-expandable command which will result in quicker code than using `\xintApplyUnbraced`. It f-expands its second (list) argument first, which may thus be encapsulated in a macro.

Rewritten in 1.09c. Nota bene: uses catcode 3 Z as privated list terminator.

```

### 3.27 `\xintFor`, `\xintFor*`, `\xintBreakFor`, `\xintBreakForAndDo`

1.09c [2013/10/09]: a new kind of loop which uses macro parameters #1, #2, #3, #4 rather than macros; while not expandable it survives executing code closing groups, like what happens in an alignment with the & character. When inserted in a macro for later use, the # character must be doubled.

The non-star variant works on a csv list, which it expands once, the star variant works on a token list, which it (repeatedly) f-expands.

1.09e adds `\XINT_forever` with `\xintintegers`, `\xintdimensions`, `\xintrationals` and `\xintBreakFor`, `\xintBreakForAndDo`, `\xintifForFirst`, `\xintifForLast`. On this occasion `\xint_firstoftwo` and `\xint_secondeoftwo` are made long.

1.09f: rewrites large parts of `\xintFor` code in order to filter the comma separated list via `\xintCSVtoList` which gets rid of spaces. The #1 in `\XINT_for_forever?` has an initial space token which serves two purposes: preventing brace stripping, and stopping the expansion made by `\xintcsvtolist`. If the `\XINT_forever` branch is taken, the added space will not be a problem there.

1.09f rewrites (2013/11/03) the code which now allows all macro parameters from #1 to #9 in `\xintFor`, `\xintFor*`, and `\XINT_forever`. 1.2i: slightly more robust `\xintifForFirst/Last` in case of nesting.

### 3.28 \XINT\_forever, \xintintegers, \xintdimensions, \xintrationals

New with 1.09e. But this used inadvertently \xintiadd/\xintimul which have the unnecessary \xintnum overhead. Changed in 1.09f to use \xintiadd/\xintimul which do not have this overhead. Also 1.09f uses \xintZapSpacesB for the \xintrationals case to get rid of leading and ending spaces in the #4 and #5 delimited parameters of \XINT\_forever\_opt\_a (for \xintintegers and \xintdimensions this is not necessary, due to the use of \numexpr resp. \dimexpr in \XINT\_?expr\_Ua, resp. \XINT\_?expr\_Da).

### 3.29 \xintForpair, \xintForthree, \xintForfour

1.09c.

[2013/11/02] 1.09f \xintForpair delegate to \xintCSVtoList and its \xintZapSpacesB the handling of spaces. Does not share code with \xintFor anymore.

[2013/11/03] 1.09f: \xintForpair extended to accept #1#2, #2#3 etc... up to #8#9, \xintForthree, #1#2#3 up to #7#8#9, \xintForfour id.

1.2i: slightly more robust \xintifForFirst/Last in case of nesting.

```

### 3.30 \xintAssign, \xintAssignArray, \xintDigitsOf

```

\xintAssign {a}{b}..{z}\to\A\B... \Z resp. \xintAssignArray {a}{b}..{z}\to\U.
\xintDigitsOf=\xintAssignArray.

1.1c 2015/09/12 has (belatedly) corrected some "features" of \xintAssign which didn't like the
case of a space right before the "\to", or the case with the first token not an opening brace and the
subsequent material containing brace groups. The new code handles gracefully these situations.

### 3.31 CSV (non user documented) variants of Length, Keep, Trim, NthElt, Reverse

These routines are for use by `\xintListSel:x:csv` and `\xintListSel:f:csv` from [xintexpr](#), and also for the `reversed` and `len` functions. Refactored for [1.2j](#) release, following [1.2i](#) updates to `\xintKeep`, `\xintTrim`, ...

These macros will remain undocumented in the user manual:

-- they exist primarily for internal use by the [xintexpr](#) parsers, hence don't have to be general purpose; for example, they a priori need to handle only catcode 12 tokens (not true in `\xintNewExpr`, though) hence they are not really worried about controlling brace stripping (nevertheless [1.2j](#) has paid some secondary attention to it, see below.) They are not worried about normalizing leading spaces either, because none will be encountered when the macros are used as auxiliaries to the expression parsers.

-- crucial design elements may change in future:

1. whether the handled lists must have or not have a final comma. Currently, the model is the one of comma separated lists with \*\*no\*\* final comma. But this means that there can not be a distinction of principle between a truly empty list and a list which contains one item which turns out to be empty. More importantly it makes the coding more complicated as it is needed to distinguish the empty list from the single-item list, both lacking commas.

For the internal use of [xintexpr](#), it would be ok to require all list items to be terminated by a comma, and this would bring quite some simplifications here, but as initially I started with non-terminated lists, I have left it this way in the [1.2j](#) refactoring.

2. the way to represent the empty list. I was tempted for matter of optimization and synchronization with [xintexpr](#) context to require the empty list to be always represented by a space token and to not let the macros admit a completely empty input. But there were complications so for the time being [1.2j](#) does accept truly empty output (it is not distinguished from an input equal to a

space token) and produces empty output for empty list. This means that the status of the «nil» object for the [xintexpr](#) parsers is not completely clarified (currently it is represented by a space token).

The original Python slicing code in [xintexpr](#) 1.1 used `\xintCSVtoList` and `\xintListWithSep{,}` to convert back and forth to token lists and apply `\xintKeep`/`\xintTrim`. Release 1.2g switched to devoted f-expandable macros added to [xinttools](#). Release 1.2j refactored all these macros as a follow-up to 1.2i improvements to `\xintKeep`/`\xintTrim`. They were made `\long` on this occasion and auxiliary `\xintLengthUpTo:f:csv` was added.

Leading spaces in items are currently maintained as is by the 1.2j macros, even by `\xintNthEltP{y:f:csv}`, with the exception of the first item, as the list is f-expanded. Perhaps `\xintNthEltPy:f:csv` should remove a leading space if present in the picked item; anyway, there are no spaces for the lists handled internally by the Python slicer of [xintexpr](#), except the «nil» object currently represented by exactly one space.

Kept items (with no leading spaces; but first item special as it will have lost a leading space due to f-expansion) will lose a brace pair under `\xintKeep:f:csv` if the first argument was positive and strictly less than the length of the list. This differs of course from `\xintKeep` (which always braces items it outputs when used with positive first argument) and also from `\xintKeepUnbraced` in the case when the whole list is kept. Actually the case of singleton list is special, and brace removal will happen then.

This behaviour was otherwise for releases earlier than 1.2j and may change again.

Directly usable names are provided, but these macros (and the behaviour as described above) are to be considered *unstable* for the time being.

### 3.31.1 `\xintLength:f:csv`

1.2g. Redone for 1.2j. Contrarily to `\xintLength` from `xintkernel.sty`, this one expands its argument.

```
1259 \def\xintLength:f:csv {\romannumeral0\xintlength:f:csv}%

### 3.31.3 \xintKeep:f:csv

1.2g 2016/03/17. Redone for 1.2j with use of `\xintLengthUpTo:f:csv`. Same code skeleton as `\xintKeep` but handling comma separated but non terminated lists has complications. The `\xintKeep` in case of a negative #1 uses `\xintgobble`, we don't have that for comma delimited items, hence we do a special loop here (this style of loop is surely competitive with `xintgobble` for a few dozens items and even more). The loop knows before starting that it will not go too far.

```

```

This strange thing is in case the picked item was the last one, hence there was an ending `\xint:` (we could not put a comma earlier for matters of not confusing empty list with a singleton list), and we do this here to activate brace-stripping of item as all other items may be brace-stripped if picked. This is done for coherence. Of course, in the context of the `xintexpr.sty` parsers, there are no braces in list items...

```

1535 \xint_firstofone{\long\def\XINT_nthelt:f:csv_pos_cleanup\xint:{} %}
1536 #1\xint:{ #1}%

```

### 3.31.6 `\xintReverse:f:csv`

1.2g. Contrarily to `\xintReverseOrder` from `xintkernel.sty`, this one expands its argument. Handles empty list too. 2016/03/17. Made `\long` for 1.2j.

```

1537 \def\xintReverse:f:csv {\romannumeral0\xintreverse:f:csv }%
1538 \long\def\xintreverse:f:csv #1%

### 3.31.10 Public names for the undocumented csv macros: `\xintCSVLength`, `\xintCSVKeep`, `\xintCSVKeepx`, `\xintCSVTrim`, `\xintCSVNthEltPy`, `\xintCSVReverse`, `\xintCSVFirstItem`, `\xintCSVLastItem`

Completely unstable macros: currently they expand the list argument and want no final comma. But for matters of *xintexpr.sty* I could as well decide to require a final comma, and then I could simplify implementation but of course this would break the macros if used with current functionalities.

```

Got split off from *xint* with release 1.1.

The core arithmetic routines have been entirely rewritten for release 1.2. The 1.2i and 1.2l brought again some improvements.

The commenting continues (2021/06/11) to be very sparse: actually it got worse than ever with release 1.2. I will possibly add comments at a later date, but for the time being the new routines are not commented at all.

1.3 removes all macros which were deprecated at 1.2o.

### 4.1 Catcodes, $\varepsilon$ - $\text{\TeX}$ and reload detection

The code for reload detection was initially copied from HEIKO OBERDIEK's packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

## 4.3 (WIP!) Error conditions and exceptions

As per the Mike Cowlishaw/IBM's General Decimal Arithmetic Specification  
<http://speleotrove.com/decimal/decarith.html>  
and the Python3 implementation in its Decimal module.  
Clamped, ConversionSyntax, DivisionByZero, DivisionImpossible, DivisionUndefined, Inexact, InsufficientStorage, InvalidContext, InvalidOperation, Overflow, Inexact, Rounded, Subnormal, Underflow.

X3.274 rajoute LostDigits  
Python rajoute FloatOperation (et n'inclut pas InsufficientStorage)  
quote de decarith.pdf: The Clamped, Inexact, Rounded, and Subnormal conditions can coincide with each other or with other conditions. In these cases then any trap enabled for another condition takes precedence over (is handled before) all of these, any Subnormal trap takes precedence

over Inexact, any Inexact trap takes precedence over Rounded, and any Rounded trap takes precedence over Clamped.

WORK IN PROGRESS ! (1.21, 2017/07/26)

I follow the Python terminology: a trapped signal means it raises an exception which for us means an expandable error message with some possible user interaction. In this WIP state, the interaction is commented out. A non-trapped signal or condition would activate a (presumably silent) handler.

Here, no signal-raising condition is "ignored" and all are "trapped" which means that error handlers are never activated, thus left in garbage state in the code.

Various conditions can raise the same signal.

Only signals, not conditions, raise Flags.

If a signal is ignored it does not raise a Flag, but it activates the signal handler (by default now no signal is ignored.)

If a signal is not ignored it raises a Flag and then if it is not trapped it activates the handler of the `_condition_`.

If trapped (which is default now) an «exception» is raised, which means an expandable error message (I copied over the LaTeX3 code for expandable error messages, basically) interrupts the TeX run. In future, user input could be solicited, but currently this is commented out.

For now macros to reset flags are done but without public interface nor documentation.

Only four conditions are currently possibly encountered:

- `InvalidOperation`
- `DivisionByZero`
- `DivisionUndefined` (which signals `InvalidOperation`)
- `Underflow`

I did it quickly, anyhow this will become more palpable when some of the Decimal Specification is actually implemented. The plan is to first do the X3.274 norm, then more complete implementation will follow... perhaps...

77          % #2

```

On 2021/05/19, 1.4g, I re-examined `\XINT_expandableerror` experimenting at first with an added `^^J` to shift to next line the actual message.

Previously I was calling it thrice (condition #2, user context #3, next tokens #5) here but it seems more reasonable to use it only once. As total size is so limited, I decided to only display #3 (information for user) and drop the #2 (condition, first argument of `\XINT_signalcondition`) and the display of the #5 (next tokens, fourth argument of `\XINT_signalcondition`).

Besides, why was I doing here `\xint_stop_atfirstofone{#5}`, which adds limitations to usage? Now inserting #5 directly so callers will have to insert a `\romannumeral0` stopping space token if needed. I thus have to update all usages across (mainly, I think) `xintfrac`. Done, but using here `\xint_firstofone{#5}`. This looks silly, but allows some hypothetical future usage by user of `I\xintUse{stuff}` usage where `\xintUse` would be `\xint_firstofthree`.

The problem is that this would have to be explained to user in the error context but space there is so extremely limited...

After having reviewed existing usage of `\XINT_signalcondition`, I noticed there was free space in most cases and added here " (hit RET)" after #3.

I experimented with `^^J` here too (its effect in the "context" is independent of the `\newlinechar` setting, but it depends on the engine: works with TeXLive pdftex, requires -8bit with xetex)

However, due to `\errorcontextlines` being 5 by default in etex (but `xintsession 0.2b` sets it to 0), I finally decided to not insert a `^^J` (&&J) at all to separate the " (hit RET)" hint.

On 2021/05/20 evening I found another completely different method for `\XINT_expandableerror`, which has some advantages. In particular it allows me to not use here "#3 (hit RET)" but simply "#3" as such information can be integrated in a non size limited generic message.

The maximal size of #3 here was increased from 48 characters (method with `\xint/` being badly delimited), to now 55 characters, longer messages being truncated at 56 characters with an appended "`\ETC.`".

```

78      \XINT_expandableerror{#3}%
79      % not for X3.274
80      \%XINT_expandableerror{<RET>, or I\xintUse{...}<RET>, or I\xintCTRLC<RET>}%

```

#### Routines handling integers as lists of token digits

Routines handling big integers which are lists of digit tokens with no special additional structure.

Some routines do not accept non properly terminated inputs like "\the\numexpr1", or "\the\mathcode`-  
", others do.

These routines or their sub-routines are mainly for internal usage.

#### 4.5 \XINT\_cuz\_small

\XINT\_cuz\_small removes leading zeroes from the first eight digits. Expands following \romannumerals0. At least one digit is produced.

```

126 \def\xINT_cuz_small#1{%
127 \def\xINT_cuz_small ##1##2##3##4##5##6##7##8%
128 {%
129   \expandafter#1\the\numexpr ##1##2##3##4##5##6##7##8\relax
130 }\}\XINT_cuz_small{ }%

```

## 4.6 \xintNum, \xintiNum

For example `\xintNum {-----0000000000000003}`

Very old routine got completely rewritten at 1.21.

New code uses `\numexpr` governed expansion and fixes some issues of former version particularly regarding inputs of the `\numexpr... \relax` type without `\the` or `\number` prefix, and/or possibly no terminating `\relax`.

`\xintiNum{\numexpr 1}\foo` in earlier versions caused premature expansion of `\foo`.

`\xintiNum{\the\numexpr 1}` was ok, but a bit luckily so.

Also, up to 1.2k inclusive, the macro fetched tokens eight by eight, and not nine by nine as is done now. I have no idea why.

`\xintNum` gets redefined by `xintfrac`.

```

131 \def\xintiNum {\romannumeral0\xintinum }%
132 \def\xintinum #1%
133 {%
134   \expandafter\XINT_num_cleanup\the\numexpr\expandafter\XINT_num_loop
135   \romannumeral`&&#1\xint:\xint:\xint:\xint:\xint:\xint:\xint:\xint:\Z
136 }%
137 \def\xintNum {\romannumeral0\xintnum }%
138 \let\xintnum\xintinum
139 \def\XINT_num #1%
140 {%
141   \expandafter\XINT_num_cleanup\the\numexpr\XINT_num_loop
142   #1\xint:\xint:\xint:\xint:\xint:\xint:\xint:\xint:\Z
143 }%
144 \def\XINT_num_loop #1#2#3#4#5#6#7#8#9%
145 {%
146   \xint_gob_til_xint: #9\XINT_num_end\xint:
147   #1#2#3#4#5#6#7#8#9%
148   \ifnum \numexpr #1#2#3#4#5#6#7#8#9+\xint_c_ = \xint_c_

```

means that so far only signs encountered, (if syntax is legal) then possibly zeroes or a terminated or not terminated `\numexpr` evaluating to zero In that latter case a correct zero will be produced in the end.

```

149   \expandafter\XINT_num_loop
150 \else
151   non terminated \numexpr (with nine tokens total) are safe as after \fi, there is then \xint:
152   \expandafter\relax
153 \fi
154 \def\XINT_num_end\xint:#1\xint:{#1+\xint_c_\xint:}%
155 \def\XINT_num_cleanup #1\xint:#2\Z { #1}%

```

## 4.7 \xintiiSgn

1.21 made `\xintiiSgn` robust against non terminated input.

1.20 deprecates here `\xintSgn` (it requires `xintfrac.sty`).

```

156 \def\xintiiSgn {\romannumeral0\xintiiisgn }%

```

## Blocks of eight digits

The lingua of release 1.2.

### 4.19 \XINT\_cuz

This (launched by `\romannumeral0`) iterately removes all leading zeroes from a sequence of 8N digits ended by `\R`.

Rewritten for 1.21, now uses `\numexpr` governed expansion and `\ifnum` test rather than delimited gobbling macros.

Note 2015/11/28: with only four digits the `\gob_til_fourzeroes` had proved in some old testing faster than `\ifnum` test. But with eight digits, the execution times are much closer, as I tested back then.

```

373 \def\XINT_cuz #1{%
374 \def\XINT_cuz {\expandafter#1\the\numexpr\XINT_cuz_loop}%
375 }\XINT_cuz{ }%

395 \def\xint_cuz_byviii_e\R #1\XINT_cuz_byviii_done #2\R{ #2}%

```

## 4.21 \XINT\_unsep\_loop

This is used as

```
\the\numexpr0\XINT_unsep_loop (blocks of 1<8digits>!)
    \xint_bye!2!3!4!5!6!7!8!9!\xint_bye\xint_c_i\relax
```

It removes the 1's and !'s, and outputs the 8N digits with a 0 token as as prefix which will have to be cleaned out by caller.

Actually it does not matter whether the blocks contain really 8 digits, all that matters is that they have 1 as first digit (and at most 9 digits after that to obey the TeX-\numexpr bound).

Done at 1.21 for usage by other macros. The similar code in earlier releases was strangely in O( $N^2$ ) style, apparently to avoid some memory constraints. But these memory constraints related to \numexpr chaining seems to be in many places in xint code base. The 1.21 version is written in the 1.2i style of \xintInc etc... and is compatible with some 1! block without digits among the treated blocks, they will disappear.

```

396 \def\xint_unsep_loop #1#!#2#!#3#!#4#!#5#!#6#!#7#!#8#!#9!%
397 }%
398     \expandafter\xint_unsep_clean

418 } }\xint_unsep_cuzsmall_x{ }%

```

#### 4.23 \XINT\_div\_unsepQ

This is used by division to remove separators from the produced quotient. The quotient is produced in the correct order. The routine will also remove leading zeroes. An extra initial block of 8 zeroes is possible and thus if present must be removed. Then the next eight digits must be cleaned of leading zeroes. Attention that there might be a single block of 8 zeroes. Expansion launched by \romannumeral0.

Rewritten for 1.21 in 1.2i style.

```

419 \def\xint_div_unsepQ_delim {\xint_bye!2!3!4!5!6!7!8!9!\xint_bye\xint_c_i\relax\Z}%

```

## 4.25 \xint\_zeroes\_forviii

```
444 \def\xint_zeroes_forviii #1#2#3#4#5#6#7#8%
445 {%
446     \xint_gob_til_R #8\xint_zeroes_forviii_end\R\xint_zeroes_forviii
447 }%
448 \def\xint_zeroes_forviii_end#1{%
449 \def\xint_zeroes_forviii_end\R\xint_zeroes_forviii ##1##2##3##4##5##6##7##8##9\W
```

```
450 {%
451     \expandafter\XINT_gob_til_one ##2##3##4##5##6##7##8%
452 }\}\XINT_zeroes_forviii_end{ }%
```

## 4.26 \XINT\_sepbyviii\_Z

This is used as

```
\the\numexpr\XINT_sepbyviii_Z <8Ndigits>\XINT_sepbyviii_Z_end 2345678\relax
```

It produces  $1<8d>!...1<8d>!1;$

Prior to 1.21 it used  $\backslash Z$  as terminator not the semi-colon (hence the name). The switch to ; was done at a time I thought perhaps I would use an internal format maintaining such 8 digits blocks, and this has to be compatible with the  $\csname...\endcsname$  encapsulation in  $\xintexpr$  parsers.

```
453 \def\XINT_sepbyviii_Z #1#2#3#4#5#6#7#8%

536 }%

```

## Core arithmetic

The four operations have been rewritten entirely for release 1.2. The new routines works with sep-
arated blocks of eight digits. They all measure first the lengths of the arguments, even addition
and subtraction (this was not the case with *xintcore.sty* 1.1 or earlier.)

The technique of chaining `\the\numexpr` induces a limitation on the maximal size depending on the
size of the input save stack and the maximum expansion depth. For the current (TL2015) settings
(5000, resp. 10000), the induced limit for addition of numbers is at 19968 and for multiplication
it is observed to be 19959 (valid as of 2015/10/07).

Side remark: I tested that `\the\numexpr` was more efficient than `\number`. But it reduced the
allowable numbers for addition from 19976 digits to 19968 digits.

### 4.33 `\xintiiAdd`

1.21: `\xintiiAdd` made robust against non terminated input.

```

537 \def\xintiiAdd {\romannumeral0\xintiiadd }%
538 \def\xintiiadd #1{\expandafter\XINT_iiadd\romannumeral`&&@#1\xint:#}%
539 \def\XINT_iiadd #1#2\xint:#3%

556     \krof #1#2%
557 }%
558 \def\XINT_add_firstiszero #1\krof 0#2#3\xint:#4\xint:{ #2#3}%
559 \def\XINT_add_secondiszero #1\krof #20#3\xint:#4\xint:{ #2#4}%
560 \def\XINT_add_minusminus #1#2%
561     {\expandafter-\romannumeral0\XINT_add_pp_a {}{}{}%}
562 \def\XINT_add_minusplus #1#2{\XINT_sub_mm_a {}#2}%
563 \def\XINT_add_plusminus #1#2%

```

2 as first token of #1 stands for "no carry", 3 will mean a carry (we are adding  $1<8\text{digits}>$  to  $1<8\text{digits}>.$ ) Version 1.2c has terminators of the shape  $1;!$ , replacing the  $\text{\Z!}$  used in 1.2.

Call:  $\backslash\text{the}\backslash\text{numexpr}\backslash\text{XINT\_add\_a } 2\#11;!1;!1;!1;\!\text{W} \#21;!1;!1;\!\text{W}$  where #1 and #2 are blocks of  $1<8d>!$ , and #1 is at most as long as #2. This last requirement is a bit annoying (if one wants to do recursive algorithms but not have to check lengths), and I will probably remove it at some point.

Output: blocks of  $1<8d>!$  representing the addition, (least significant first), and a final  $1;!$ . In recursive algorithm this  $1;!$  terminator can thus conveniently be reused as part of input terminator (up to the length problem).

## 4.35 \xintiiSub

Entirely rewritten for 1.2.

Refactored at 1.21. I was initially aiming at clinching some internal format of the type  $1<8\text{digits}>!\dots!1<8\text{digits}>!$  for chaining the arithmetic operations (as a preliminary step to deciding upon some internal format for *xintfrac* macros), thus I wanted to uniformize delimiters in particular and have some core macros inputting and outputting such formats. But the way division is implemented makes it currently very hard to obtain a satisfactory solution. For subtraction I got there almost, but there was added overhead and, as the core sub-routine still assumed the shorter number will be positioned first, one would need to record the length also in the basic internal format, or add the overhead to not make assumption on which one is shorter. I thus but back-tracked my steps but in passing I improved the efficiency (probably) in the worst case branch.

Sadly this 1.21 refactoring left an extra ! in macro \XINT\_sub\_l\_Ida. This bug shows only in rare circumstances which escaped out test suite :( Fixed at 1.2q.

The other reason for backtracking was in relation with the decimal numbers. Having a core format in base  $10^8$  but ultimately the radix is actually 10 leads to complications. I could use radix  $10^8$  for \xintiiexpr only, but then I need to make it compatible with sub-\xintiiexpr in \xintexpr, etc... there are many issues of this type.

I considered also an approach like in the 1.21 \xintiiCmp, but decided to stick with the method here for now.

The post-processing (clean-up of zeros, or rescue of situation with A-B where actually B turns out bigger than A) will be done by a macro which depends on circumstances and will be initially last token before the reversion done by \XINT\_unrevbyviii.

```

854 \def\xint_sub_out {\XINT_unrevbyviii{}}
1 as first token of #1 stands for "no carry", 0 will mean a carry.
Call: \the\numexpr
      \XINT_sub_a 1#11;!1;!1;!1;\W
      #21;!1;!1;!1;\W

```

where #1 and #2 are blocks of  $1<8d>!$ , #1 (=B) \*must\* be at most as long as #2 (=A), (in radix  $10^8$ ) and the routine wants to compute  $#2 - #1 = A - B$

1.21 uses 1;! delimiters to match those of addition (and multiplication). But in the end I reverted the code branch which made it possible to chain such operations keeping internal format in 8 digits blocks throughout.

\numexpr governed expansion stops with various possibilities:

- Type Ia: #1 shorter than #2, no final carry
- Type Ib: #1 shorter than #2, a final carry but next block of #2 > 1
- Type Ica: #1 shorter than #2, a final carry, next block of #2 is final and = 1
- Type Icb: as Ica except that 00000001 block from #2 was not final
- Type Id: #1 shorter than #2, a final carry, next block of #2 = 0
- Type IIa: #1 same length as #2, turns out it was  $\leq #2$ .
- Type IIb: #1 same length as #2, but turned out  $> #2$ .

Various type of post actions are then needed:

- Ia: clean up of zeros in most significant block of 8 digits
- Ib: as Ia
- Ic: there may be significant blocks of 8 zeros to clean up from result. Only case Ica may have arbitrarily many of them, case Icb has only one such block.
- Id: blocks of 99999999 may propagate and there might a be final zero block created which has to be cleaned up.
  - IIa: arbitrarily many zeros might have to be removed.
  - IIb: We wanted  $#2 - #1 = - (#1 - #2)$ , but we got  $10^{8N} + #2 - #1 = 10^{8N} - (#1 - #2)$ . We need to do the correction then we are as in IIa situation, except that final result can not be zero.

The 1.21 method for this correction is (presumably, testing takes lots of time, which I do not have) more efficient than in 1.2 release.

B terminated. Have we reached the end of A (necessarily at least as long as B) ? (we are computing A-B, digits of B come first).

If not, then we are certain that even if there is carry it will not propagate beyond the end of A. But it may propagate far transforming chains of 0000000 into 99999999, and if it does go to the final block which possibly is just  $1<00000001>!$ , we will have those eight zeros to clean up.

If A and B have the same length (in base  $10^8$ ) then arbitrarily many zeros might have to be cleaned up, and if  $A < B$ , the whole result will have to be complemented first.

This is the case where both operands have same  $10^8$ -base length.

We were handling A-B but perhaps B>A. The situation with A=B is also annoying because we then have to clean up all zeros but don't know where to stop (if A>B the first non-zero 8 digits block would tell use when).

Here again we need to grab #3\W to position the actually used terminating delimiters.

## 4.36 \xintiiMul

Completely rewritten for 1.2.

1.21: `\xintiiMul` made robust against non terminated input.

Call:

```
\the\numexpr \XINT_mul_loop 100000000!1;!W #11;!W #21;!W #21;
```

where #1 and #2 are (globally reversed) blocks  $1 < 8d > !$ . Its is generally more efficient if #1 is the shorter one, but a better recipe is implemented in `\XINT_mul_checklengths`. One may call `\XINT_mul_loop` directly (but multiplication by zero will produce many  $100000000!$  blocks on output).

Ends after having produced:  $1<8d>!....1<8d>!1!!$ . The last 8-digits block is significant one. It can not be 100000000! except if the loop was called with a zero operand.

Thus `\XINT_mul_loop` can be conveniently called directly in recursive routines, as the output terminator can serve as input terminator, we can arrange to not have to grab the whole thing again.

```

```

1.2 small and mini multiplication in base  $10^8$  with carry. Used by the main multiplication routines. But division, float factorial, etc.. have their own variants as they need output with specific constraints.

The `minimulwc` has  $1<8\text{digits carry}>. <4 \text{ high digits}>. <4 \text{ low digits!}<8\text{digits}>$ .

It produces a block  $1<8d>!$  and then jump back into `\XINT_smallmul_a` with the new 8digits carry as argument. The `\XINT_smallmul_a` fetches a new  $1<8d>!$  block to multiply, and calls back `\XINT_minimul_wc` having stored the multiplicand for re-use later. When the loop terminates, the final carry is checked for being nul, and in all cases the output is terminated by a 1;!

Multiplication by zero will produce blocks of zeros.

```

## 4.37 \xintiiDivision

Completely rewritten for 1.2.

WARNING: some comments below try to describe the flow of tokens but they date back to xint 1.09j and I updated them on the fly while doing the 1.2 version. As the routine now works in base 10^8, not 10^4 and "drops" the quotient digits, rather than store them upfront as the earlier code, I may well have not correctly converted all such comments. At the last minute some previously #1 became stuff like #1#2#3#4, then of course the old comments describing what the macro parameters stand for are necessarily wrong.

Side remark: the way tokens are grouped was not essentially modified in 1.2, although the situation has changed. It was fine-tuned in xint 1.0/1.1 but the context has changed, and perhaps I should revisit this. As a corollary to the fact that quotient digits are now left behind thanks to the chains of \numexpr, some macros which in 1.0/1.1 fetched up to 9 parameters now need handle less such parameters. Thus, some rationale for the way the code was structured has disappeared.

1.21: \xintiiDivision et al. made robust against non terminated input.

#1 = A, #2 = B. On calcule le quotient et le reste dans la division euclidienne de A par B: A=BQ+R,  $0 \leq R < |B|$ .

Donc attention malgré son nom \XINT\_div\_prepare va jusqu'au bout. C'est donc en fait l'entrée principale (pour  $B>0$ ,  $A>0$ ) mais elle va regarder si  $B$  est  $< 10^8$  et s'il vaut alors 1 ou 2, et si  $A < 10^8$ . Dans tous les cas le résultat est produit sous la forme  $\{Q\}\{R\}$ , avec  $Q$  et  $R$  sous leur forme final. On doit ensuite ajuster si le  $B$  ou le  $A$  initial était négatif. Je n'ai pas fait beaucoup d'efforts pour être un minimum efficace si  $A$  ou  $B$  n'est pas positif.

Ici  $B < 10^8$  (et est  $> 2$ ). On exécute  
 $\expandafter\XINT_sdiv_out\the\numexpr\XINT_smalldivx_a x.1B!1<8d>!\dots1<8d>!1;!$   
 avec  $x = \text{round}(B/2)$ ,  $1B = 10^8 + B$ , et  $A$  déjà en blocs  $1<8d>!$  (non renversés). Le  $\the\numexpr\XINT_smalldivx_a$   
 va produire  $Q\backslash Z R\backslash W$  avec un  $R < 10^8$ , et un  $Q$  sous forme de blocs  $1<8d>!$  terminé par  $1!$  et nécessi-  
 tant le nettoyage du premier bloc. Dans cette branche le  $B$  n'a pas été multiplié par une puissance  
 de 10, il peut avoir moins de huit chiffres.

```

Cette routine fait la division euclidienne d'un nombre de seize chiffres par #1 = C = diviseur sur huit chiffres  $\geq 10^7$ , avec #2 = sa moitié utilisée dans \numexpr pour contrebalancer l'arrondi (ARRRRRRGGGGHHHH) fait par /. Le nombre divisé XY = X\* $10^8$ +Y se présente sous la forme 1<8chiffres>!1<8chiffres>! avec plus significatif en premier.

Seul le quotient est calculé, pas le reste. En effet la routine de division principale va utiliser ce quotient pour déterminer le "grand" reste, et le petit reste ici ne nous serait d'à peu près aucune utilité.

ATTENTION UNIQUEMENT UTILISÉ POUR DES SITUATIONS OÙ IL EST GARANTI QUE X < C ! (et C au moins  $10^7$ ) le quotient euclidien de X\* $10^8$ +Y par C sera donc <  $10^8$ . Il sera renvoyé sous la forme 1<8chiffres>.

## 4.46 \xintiiPow

The exponent is not limited but with current default settings of tex memory, with xint 1.2, the maximal exponent for  $2^N$  is  $N = 2^{17} = 131072$ .

1.2f Modifies the initial steps: 1) in order to be able to let more easily `\xintiPow` use `\xintNum` on the exponent once `xintfrac.sty` is loaded; 2) also because I noticed it was not very well coded. And it did only a `\numexpr` on the exponent, contradicting the documentation related to the "i" convention in names.

1.21: `\xintiiPow` made robust against non terminated input.

## 4.47 \xintiiFac

Moved here from xint.sty with release 1.2 (to be usable by \bnumexpr).

An `\xintiFac` is needed by `xintexpr.sty`. Prior to 1.2o it was defined here as an alias to `\xintiiFac`, then redefined by `xintfrac` to use `\xintNum`. This was incoherent. Contrarily to other similarly named macros, `\xintiiFac` uses `\numexpr` on its input. This is also incoherent with the naming scheme, alas.

Partially rewritten with release 1.2 to benefit from the inner format of the 1.2 multiplication.

With current default settings of the etex memory and a.t.t.o.w (11/2015) the maximal possible computation is 5971! (which has 19956 digits).

Note (end november 2015): I also tried out a quickly written recursive (binary split) implementation

With release 1.1 the core arithmetic routines *\xintiiAdd*, *\xintiiSub*, *\xintiiMul*, *\xintiiQuo*, *\xintiiPow* were separated to be the main component of the then new *xintcore*.

At 1.3 the macros deprecated at 1.20 got all removed.

1.3b adds randomness related macros.

## 5.4 \xintLen, \xintiLen

\xintLen gets extended to fractions by *xintfrac.sty*: A/B is given length  $\text{len}(A)+\text{len}(B)-1$  (somewhat arbitrary). It applies \xintNum to its argument. A minus sign is accepted and ignored.

For parallelism with \xintiNum/\xintNum, 1.2o defines \xintiLen.

\xintLen gets redefined by *xintfrac*.

```

```

## 5.6 \xintReverseDigits

1.2.

This puts digits in reverse order, not suppressing leading zeros after reverse. Despite lacking the "ii" in its name, it does not apply \xintNum to its argument (contrarily to \xintLen, this is not very coherent).

1.2l variant is robust against non terminated \the\numexpr input.

This macro is currently not used elsewhere in xint code.

## 5.7 \xintiiE

Originally was used in `\xintiiexpr`. Transferred from `xintfrac` for 1.1. Code rewritten for 1.2i. `\xintiiE{x}{e}` extends `x` with `e` zeroes if `e` is positive and simply outputs `x` if `e` is zero or negative. Attention, le comportement pour  $e < 0$  ne doit pas être modifié car `\xintMod` et autres macros en dépendent.

```

```

## 5.8 \xintDecSplit

### DECIMAL SPLIT

The macro `\xintDecSplit {x}{A}` cuts A which is composed of digits (leading zeroes ok, but no sign) (\*) into two (each possibly empty) pieces L and R. The concatenation LR always reproduces A.

The position of the cut is specified by the first argument x. If x is zero or positive the cut location is x slots to the left of the right end of the number. If x becomes equal to or larger than the length of the number then L becomes empty. If x is negative the location of the cut is |x| slots to the right of the left end of the number.

(\*) versions earlier than 1.2i first replaced A with its absolute value. This is not the case anymore. This macro should NOT be used for A with a leading sign (+ or -).

Entirely rewritten for 1.2i (2016/12/11).

Attention: `\xintDecSplit` not robust against non terminated second argument.

## 5.11 \xintDSHr

DECIMAL SHIFTS \xintDSH {x}{A}  
 si  $x \leq 0$ , fait  $A \rightarrow A \cdot 10^{|x|}$ . si  $x > 0$ , et  $A \geq 0$ , fait  $A \rightarrow \text{quo}(A, 10^x)$   
 si  $x > 0$ , et  $A < 0$ , fait  $A \rightarrow -\text{quo}(-A, 10^x)$   
 (donc pour  $x > 0$  c'est comme DSR itéré  $x$  fois)  
 $\xintDSHr$  donne le 'reste' (si  $x \leq 0$  donne zéro).  
 Badly named macros.  
 Rewritten for 1.2i, this was old code and \xintDSx has changed interface.

```

### 5.13 \xintDSx

--> Attention le cas  $x=0$  est traité dans la même catégorie que  $x > 0$ --  
 si  $x < 0$ , fait  $A \rightarrow A \cdot 10^{|x|}$   
 si  $x \geq 0$ , et  $A \geq 0$ , fait  $A \rightarrow \{ \text{quo}(A, 10^x) \} \{ \text{rem}(A, 10^x) \}$   
 si  $x \geq 0$ , et  $A < 0$ , d'abord on calcule  $\{ \text{quo}(-A, 10^x) \} \{ \text{rem}(-A, 10^x) \}$   
 puis, si le premier n'est pas nul on lui donne le signe -  
 si le premier est nul on donne le signe - au second.

On peut donc toujours reconstituer l'original  $A$  par  $10^x Q \pm R$  où il faut prendre le signe plus si  $Q$  est positif ou nul et le signe moins si  $Q$  est strictement négatif.

Rewritten for 1.2i, this was old code.

509     \fi
510 }%

```

### 5.38 \xintifTrueAelseB, \xintifFalseAelseB

1.09i. 1.2i has removed deprecated \xintifTrueFalse, \xintifTrue.

1.2o uses \xintiiifNotZero, see comments to \xintAND etc... This will work fine with arguments being nested *xintfrac.sty* macros, without the overhead of \xintNum or \xintRaw parsing.

```

511 \def\xintifTrueAelseB {\romannumeral0\xintiiifnotzero}%
512 \def\xintifFalseAelseB{\romannumeral0\xintiiifzero}%

```

### 5.39 \xintIsTrue, \xintIsFalse

1.09c. Suppressed at 1.2o. They seem not to have been documented, fortunately.

```

513 %\let\xintIsTrue \xintIsNotZero
514 %\let\xintIsFalse\xintIsZero

```

### 5.40 \xintNOT

1.09c. But it should have been called \xintNOT, not \xintNot. Former denomination deprecated at 1.2o. Besides, the macro is now defined as ii-type.

```

515 \def\xintNOT{\romannumeral0\xintiiiszero}%

```

### 5.41 \xintAND, \xintOR, \xintXOR

Added with 1.09a. But they used \xintSgn, etc... rather than \xintiiSgn. This brings \xintNum overhead which is not really desired, and which is not needed for use by *xintexpr.sty*. At 1.2o I modify them to use only ii macros. This is enough for sign or zeroness even for *xintfrac* format, as manipulated inside the \xintexpr. Big hesitation whether there should be however \xintiiAND outputting 1 or 0 versus an \xintAND outputting 1[0] versus 0[0] for example.

```

```

## 5.42 \xintANDof

New with 1.09a. \xintANDof works also with an empty list. Empty items however are not accepted.

1.21 made \xintANDof robust against non terminated items.

1.20's \xintifTrueAelseB is now an ii macro, actually.

1.4. This macro as well as ORof and XORof were formally not used by xintexpr, which uses comma separated items, but at 1.4 xintexpr uses braced items. And the macros here got slightly refactored and XINT\_ANDof added for usage by xintexpr and the NewExpr hook. For some random reason I decided to use ^ as delimiter this has to do that other macros in xintfrac in same family (such as \xintGCDof, \xintSum) also use \xint: internally and although not strictly needed having two separate ones clarifies.

```

## 5.50 \xintiiPrd

*\xintiiPrd {{a}}...{z}}*

Macros renamed and refactored (slightly more macros here to supposedly bring micro-gain) at 1.4 to match changes in *xintfrac* of delimiter, in sync with some usage in *xintexpr*.

Contrarily to the *xintfrac* version *\xintPrd*, this one aborts as soon as it hits a zero value.

```
696 \def\xintiiPrd {\romannumeral0\xintiiprd }%
```

```
697 \def\xintiiprd #1{\expandafter\XINT_iiprd\romannumeral`&&@#1^}%
698 \def\XINT_iiprd{\romannumeral0\XINT_iiprd}%
```

The above *romannumeral* caused f-expansion of the list argument. We f-expand below the first item and each successive items because we do not use *\xintiimul* but jump directly into *\XINT\_mul\_nfork*.

```

## 5.51 *\xintiiSquareRoot*

First done with 1.08.

1.1 added *\xintiiSquareRoot*.  
1.1a added *\xintiiSqrtR*.

1.2f (2016/03/01-02-03) has rewritten the implementation, the underlying mathematics remaining about the same. The routine is much faster for inputs having up to 16 digits (because it does it all with *\numexpr* directly now), and also much faster for very long inputs (because it now fetches only the needed new digits after the first 16 (or 17) ones, via the geometric sequence 16, then 32, then 64, etc...; earlier version did the computations with all remaining digits after a suitable starting point with correct 4 or 5 leading digits). Note however that the fetching of tokens is via intrinsically O( $N^2$ ) macros, hence inevitably inputs with thousands of digits start being treated less well.

Actually there is some room for improvements, one could prepare better input X for the upcoming treatment of fetching its digits by 16, then 32, then 64, etc...

Incidentally, as *\xintiiSqrt* uses subtraction and subtraction was broken from 1.2 to 1.2c, then for another reason from 1.2c to 1.2f, it could get wrong in certain (relatively rare) cases. There was also a bug that made it unnecessarily slow for odd number of digits on input.

1.2f also modifies *\xintFloatSqrt* in *xintfrac.sty* which now has more code in common with here and benefits from the same speed improvements.

1.2k belatedly corrects the output to {1}{1} and not 11 when input is zero. As braces are used in all other cases they should have been used here too.

Also, 1.2k adds an `\xintiSqrtR` macro, for coherence as `\xintiSqrt` is defined (and mentioned in user manual.)

## 5.53 \xintiiBinomial

2015/11/28-29 for 1.2f.

2016/11/19 for 1.2h: I truly can't understand why I hard-coded last year an error-message for arguments outside of the range for binomial formula. Naturally there should be no error but a rather a 0 return value for binomial(x,y), if y<0 or x<y !

I really lack some kind of infinity or NaN value.

1.2o deprecates \xintiBinomial. (which xintfrac.sty redefined to use \xintNum)

```

`y=x-k+1.j=1.k.` On va évaluer par  $y/1*(y+1)/2*(y+2)/3$  etc... On essaie de regrouper de manière à utiliser au mieux `\numexpr`. On peut aller jusqu'à  $x=10000$  car  $9999*10000 < 10^8$ .  $463*464*465 = 99896880$ ,  $98*99*100*101 = 97990200$ . On va vérifier à chaque étape si on dépasse un seuil. Le style de l'implémentation diffère de celui que j'avais utilisé pour `\xintiiFac`. On pourrait tout-à-fait avoir une `verybigloop`, mais bon. Je rajoute aussi un `verysmall`. Le traitement est un peu différent pour elle afin d'aller jusqu'à  $x=29$  (et pas seulement 26 si je suivais le modèle des autres, mais je veux pouvoir faire `binomial(29,1)`, `binomial(29,2)`, ... en `vsmall`).

```

y.j.k. La partie very small. y est au plus 26 (non 29 mais retesté dans \XINT\_binom\_vsmallloop\_a), et tous les binomial(29,n) sont <10^8. On peut donc faire y(y+1)(y+2)(y+3) et aussi il y a le fait que etex fait a\*b/c en double precision. Pour ne pas bifurquer à la fin sur smallloop, si n=27, 27, ou 29 on procède un peu différemment des autres boucles. Si je testais aussi #1 après #3-#2 pour les autres il faudrait des terminaisons différentes.

## 5.54 \xintiiPFactorial

2015/11/29 for 1.2f. Partial factorial pfac(a,b)=(a+1)...b, only for non-negative integers with a<=b<10^8.

1.2h (2016/11/20) removes the non-negativity condition. It was a bit unfortunate that the code raised `\xintError:OutOfRangePFac` if  $0 \leq a \leq b < 10^8$  was violated. The rule now applied is to interpret `pfac(a,b)` as the product for  $a < j \leq b$  (not as a ratio of Gamma function), hence if  $a \geq b$ , return 1 because of an empty product. If  $a < b$ : if  $a < 0$ , return 0 for  $b \geq 0$  and  $(-1)^{b-a}$  times  $|b| \dots (|a|-1)$  for  $b < 0$ . But only for the range  $0 \leq a \leq b < 10^8$  is the macro result to be considered as stable.

```

```

## 5.56 \xintiiGCD

1.3d: *\xintiiGCD* code from *xintgcd* is copied here to support *gcd()* function in *\xintiiexpr*.

1.4: removed from *xintgcd* the original caode as now *xintgcd* loads *xint*.

1.4d (2021/03/29) [commented 2021/03/22]. Damn'ed! Since 1.3d (2019/01/06) the code was broken if one of the arguments vanished due to a typo in macro names: "AisZero" at one location and "Aiszero" at next, and same for B... .

How could this not be detected by my tests !?

This caused *\xintiiGCDof* hence the *gcd()* function in *\xintiiexpr* to break as soon as one argument was zero.

```

## 5.57 \xintiiGCDof

New with 1.09a (was located in *xintgcd.sty*).

1.21 adds protection against items being non-terminated *\the\numexpr*.

1.4 renames the macro into *\xintiiGCDof* and moves it here. Terminator modified to ^ for direct call by *\xintiiexpr* function.

1.4d fixes breakage inherited since 1.3d rom *\xintiiGCD*, in case any argument vanished.

Currently does not support empty list of arguments.

```

1581 }%

```

This raises following annex question: immediately after setting the seed is it possible for `\xintUniformDeviate{N}` where  $N > 0$  has exactly eight digits to return either 0 or  $N-1$ ? It could be that this is never the case, then there is a bias in `randrange()`. Of course there are anyhow only  $2^{28}$  seeds so `randrange(10^X)` is by necessity biased when executed immediately after setting the seed, if  $X$  is at least 9.

```

1582 \def\XINT_randrange_d #1\xint:#2\xint:

```

This is quite unlikely to get executed but if it does it must pay attention to leading zeros, hence the `\xintinum`. We don't have to be overly obstinate about removing overheads...

```

1593 \def\XINT_randrange_Z 0\xint:#1\xint:#2\xint:
1594 {%
1595     \xintinum{\xintRandomDigits{#1-\xint_c_viii}}%
1596 }%

```

Here too, overhead is not such a problem. The idea is that we got by extraordinary same first 8 digits as upper range bound so we pick at random the remaining needed digits in one go and compare with the upper bound. If too big, we start again with another random 8 leading digits in given range. No need to aim at any kind of efficiency for the check and loop back.

## 6 Package *xintbinhex* implementation

.1	Catcodes, $\varepsilon$ - $\text{\TeX}$ and reload detection . . . . .	164	.6	$\backslash$ xintDecToBin . . . . .	169
.2	Package identification . . . . .	165	.7	$\backslash$ xintHexToDec . . . . .	170
.3	Constants, etc... . . . . .	165	.8	$\backslash$ xintBinToDec . . . . .	172
.4	Helper macros . . . . .	166	.9	$\backslash$ xintBinToHex . . . . .	173
.4.1	$\backslash$ XINT_zeroes_foriv . . . . .	166	.10	$\backslash$ xintHexToBin . . . . .	174
.5	$\backslash$ xintDecToHex . . . . .	166	.11	$\backslash$ xintCHexToBin . . . . .	174

The commenting is currently (2021/06/11) very sparse.

The macros from 1.08 (2013/06/07) remained unchanged until their complete rewrite at 1.2m (2012/07/31).

At 1.2n dependencies on *xintcore* were removed, so now the package loads only *xintkernel* (this could have been done earlier).

Also at 1.2n, macros evolved again, the main improvements being in the increased allowable sizes of the input for  $\backslash$ xintDecToHex,  $\backslash$ xintDecToBin,  $\backslash$ xintBinToHex. Use of  $\backslash$ csname governed expansion at some places rather than  $\backslash$ numexpr with some clean-up after it.

### 6.1 Catcodes, $\varepsilon$ - $\text{\TeX}$ and reload detection

The code for reload detection was initially copied from HEIKO OBERDIEK's packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

135   #5#6#7#8!\XINT_dthb_exclam\relax\XINT_dthb_nextfour #9%
136 }%

```

The 1.2n inserted exclamations marks, which when bumping back from `\XINT_dthb_again` gave rise to a `\numexpr`-loop which gathered the ! delimited arguments and inserted `\expandafter\XINT_dthb_update\the\numexpr` dynamically. The 1.2o trick is to insert it here immediately. Then at `\XINT_dthb_again` the `\numexpr` will trigger an already prepared chain.

The crux of the thing is handling of #3 at `\XINT_dthb_update_a`.

```

137 \def\XINT_dthb_exclam {!\XINT_dthb_exclam\relax
138                           \expandafter\XINT_dthb_update\the\numexpr}%

## 6.7 `\xintHexToDec`

Completely (and belatedly) rewritten at 1.2m in the 1.2 style.

1.2m version robust against non terminated inputs, but there is no primitive from TeX which may generate hexadecimal digits and provoke expansion ahead, afaik, except of course if decimal digits are treated as hexadecimal. This robustness is not on purpose but from need to expand argument and then grab it again. So we do it safely.

Increased maximal size at 1.2n.

1.2m version robust against non terminated inputs.

An input without leading zeroes gives an output without leading zeroes.

```

It is a bit annoying to grab all to the end here. I have a version, modeled on the 1.2n variant of *\xintDecToHex* which solved that problem there, but it did not prove enough if at all faster in my brief testing and it had the defect of a reduced maximal allowed size of the input.

```

## 6.9 **\xintBinToHex**

Complete rewrite for 1.2m. But input for 1.2m version limited to about 13320 binary digits (expansion depth=10000).

Again redone for 1.2n for \csname governed expansion: increased maximal size.

Size of output is ceil(size(input)/4), leading zeroes in output (inherited from the input) are not trimmed.

An input without leading zeroes gives an output without leading zeroes.

Robust against non-terminated input.

```

```

424 }%

## 6.10 \xintHexToBin

Completely rewritten for 1.2m.

Attention this macro is not robust against arguments expanding after themselves.

Only up to three zeros are removed on front of output: if the input had a leading zero, there will be a leading zero (and then possibly 4n of them if inputs had more leading zeroes) on output.

Rewritten again at 1.2n for \csname governed expansion.

```
425 \def\xintHexToBin {\romannumeral0\xinthextobin }%

## 7 Package *xintgcd* implementation

.1	Catcodes, $\varepsilon$ - $\text{\TeX}$ and reload detection . . . . .	176	.5	$\backslash$ xintBezoutAlgorithm . . . . .	182
.2	Package identification . . . . .	177	.6	$\backslash$ xintTypesetEuclideAlgorithm . . . . .	184
.3	$\backslash$ xintBezout . . . . .	177	.7	$\backslash$ xintTypesetBezoutAlgorithm . . . . .	185
.4	$\backslash$ xintEuclideAlgorithm . . . . .	181			

The commenting is currently (2021/06/11) very sparse.

Release 1.09h has modified a bit the  $\backslash$ xintTypesetEuclideAlgorithm and  $\backslash$ xintTypesetBezoutAlgorithm layout with respect to line indentation in particular. And they use the *xinttools*  $\backslash$ xintloop rather than the Plain  $\text{\TeX}$  or  $\text{\LaTeX}$ 's  $\backslash$ loop.

Breaking change at 1.2p:  $\backslash$ xintBezout{A}{B} formerly had output {A}{B}{U}{V}{D} with AU-BV=D, now it is {U}{V}{D} with AU+BV=D.

From 1.1 to 1.3f the package loaded only *xintcore*. At 1.4 it now automatically loads both of *xint* and *xinttools* (the latter being in fact a requirement of  $\backslash$ xintTypesetEuclideAlgorithm and  $\backslash$ xintTypesetBezoutAlgorithm since 1.09h).

At 1.4  $\backslash$ xintGCD,  $\backslash$ xintLCM,  $\backslash$ xintGCDof, and  $\backslash$ xintLCMof are removed from the package: they are provided only by *xintfrac* and they handle general fractions, not only integers.

Changed  
at 1.4!

The original integer-only macros have been renamed into respectively  $\backslash$ xintiiGCD,  $\backslash$ xintiiLCM,  $\backslash$ xintiiGCDof, and  $\backslash$ xintiiLCMof and got relocated into *xint* package.

### 7.1 Catcodes, $\varepsilon$ - $\text{\TeX}$ and reload detection

The code for reload detection was initially copied from HEIKO OBERDIEK's packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

52 \ProvidesPackage{xintgcd}%
53 [2021/06/11 v1.4i Euclide algorithm with xint package (JFB)]%

```

## 7.3 \xintBezout

\xintBezout{#1}{#2} produces {U}{V}{D} with  $UA+VB=D$ ,  $D = \text{PGCD}(A, B)$  (non-positive), where #1 and #2 f-expand to big integers A and B.

I had not checked this macro for about three years when I realized in January 2017 that \xintBezout{A}{B} was buggy for the cases  $A = 0$  or  $B = 0$ . I fixed that blemish in 1.2l but overlooked the other blemish that \xintBezout{A}{B} with A multiple of B produced a coefficient U as -0 in place of 0.

Hence I rewrote again for 1.2p. On this occasion I modified the output of the macro to be {U}{V}{D} with  $AU+BV=D$ , formerly it was {A}{B}{U}{V}{D} with  $AU - BV = D$ . This is quite breaking change!

Note in particular change of sign of V.

I don't know why I had designed this macro to contain {A}{B} in its output. Perhaps I initially intended to output {A//D}{B//D} (but forgot), as this is actually possible from outcome of the last iteration, with no need of actually dividing. Current code however arranges to skip this last update, as U and V are already furnished by the iteration prior to realizing that the last non-zero remainder was found.

Also 1.2l raised `InvalidOperationException` if both A and B vanished, but I removed this behaviour at 1.2p.

    e = -e
puis calcul quotient reste et itération
We arrange for \xintiiMul sub-routine to be called only with positive arguments, thus skipping some un-needed sign parsing there. For that though we have to screen out the special cases A divides B, or B divides A. And we first want to exchange A and B if A < B. These special cases are the only one possibly leading to U or V zero (for A and B positive which is the case here.) Thus the general case always leads to non-zero U and V's and assigning a final sign is done simply adding a - to one of them, with no fear of producing -0.

We use the fact that the `\romannumeral`0` (or equivalent) done by `\xintiiadd` will absorb the initial space token left by `\XINT_mul_plusplus` in its output.

We arranged for operands here to be always positive which is needed for `\XINT_mul_plusplus` entry point (last time I checked...). Admittedly this kind of optimization is not good for maintenance of code, but I can't resist temptation of limiting the shuffling around of tokens...

## 7.7 \xintTypesetBezoutAlgorithm

Pour Bezout on a: {N}{A}{0}{1}{D=r(n)}{B}{1}{0}{q1}{r1}{alpha1=q1}{beta1=1}

{q2}{r2}{alpha2}{beta2}....{qN}{rN=0}{alphaN=A/D}{betaN=B/D}

Donc  $4N+8$  termes:  $U_1 = N$ ,  $U_2 = A$ ,  $U_5 = D$ ,  $U_6 = B$ ,  $q_1 = U_9$ ,  $q_n = U_{4n+5}$ ,  $n$  au moins 1

$r_n = U_{4n+6}$ ,  $n$  au moins -1

$\alpha(n) = U_{4n+7}$ ,  $n$  au moins -1

$\beta(n) = U_{4n+8}$ ,  $n$  au moins -1

1.09h uses `\xintloop`, and `\par` rather than `\endgraf`; and no more `\parindent0pt`

```

## 8.1 Catcodes, $\varepsilon$ - $\text{\TeX}$ and reload detection

The code for reload detection was initially copied from HEIKO OBERDIEK's packages, then modified.  
The method for catcodes was also initially directly inspired by these packages.

```

1 \begingroup\catcode61\catcode48\catcode32=10\relax%
2   \catcode13=5      % ^^M

## 8.2 Package identification

```
44 \XINT_providespackage
45 \ProvidesPackage{xintfrac}%
46 [2021/06/11 v1.4i Expandable operations on fractions (JFB)]%
```

## 8.3 \XINT\_cntSgnFork

1.09i. Used internally, #1 must expand to  $\text{\m@ne}$ ,  $\text{\z@}$ , or  $\text{\@ne}$  or equivalent. *\XINT\_cntSgnFork* does not insert a roman numeral stopper.

```
47 \def\XINT_cntSgnFork #1%
48 {%
49     \ifcase #1\expandafter\xint_secondeofthree
50         \or\expandafter\xint_thirdeofthree
51         \else\expandafter\xint_firsteofthree
52     \fi
53 }%
```

## 8.4 \xintLen

The used formula is disputable, the idea is that  $A/1$  and  $A$  should have same length. Venerable code rewritten for 1.2i, following updates to *\xintLength* in *xintkernel.sty*. And sadly, I forgot on this occasion that this macro is not supposed to count the sign... Fixed in 1.2k.

```
54 \def\xintLen {\romannumeral0\xintlen }%
55 \def\xintlen #1%
56 {%
57     \expandafter\XINT_flen\romannumeral0\XINT_infrac {#1}%
58 }%
59 \def\XINT_flen#1{\def\XINT_flen ##1##2##3%

66     \relax
67 }}\XINT_flen{ }%
```

## 8.5 \XINT\_outfrac

Months later (2014/10/22): perhaps I should document what this macro does before I forget? from  $\{e\}\{N\}\{D\}$  it outputs  $N/D[e]$ , checking in passing if  $D=0$  or if  $N=0$ . It also makes sure  $D$  is not  $< 0$ . I am not sure but I don't think there is any place in the code which could call *\XINT\_outfrac* with a  $D < 0$ , but I should check.

```
68 \def\XINT_outfrac #1#2#3%
69 {%
70     \ifcase\XINT_cntSgn #3\xint:
71         \expandafter \XINT_outfrac_divisionbyzero

## 8.6 \XINT\_inFrac

Parses fraction, scientific notation, etc... and produces  $\{n\}\{A\}\{B\}$  corresponding to A/B times  $10^n$ . No reduction to smallest terms.

Extended in 1.07 to accept scientific notation on input. With lowercase e only. The *\xintexpr* parser does accept uppercase E also. Ah, by the way, perhaps I should at least say what this macro does? (belated addition 2014/10/22...), before I forget! It prepares the fraction in the internal format  $\{\text{exponent}\}\{\text{Numerator}\}\{\text{Denominator}\}$  where Denominator is at least 1.

2015/10/09: this venerable macro from the very early days (1.03, 2013/04/14) has gotten a lifting for release 1.2. There were two kinds of issues:

1) use of \W, \Z, \T delimiters was very poor choice as this could clash with user input,  
 2) the new \XINT\_frac\_gen handles macros (possibly empty) in the input as general as \A.\Be\C\D.\Ee\F.  
 The earlier version would not have expanded the \B or \E: digits after decimal mark were constrained to arise from expansion of the first token. Thus the 1.03 original code would have expanded only \A, \D, \C, and \F for this input.

This reminded me think I should revisit the remaining earlier portions of code, as I was still learning TeX coding when I wrote them.

Also I thought about parsing even faster the A/B[N] input, not expanding B, but this turned out to clash with some established uses in the documentation such as 1/\xintiiSqr{...}[0]. For the implementation, careful here about potential brace removals with parameter patterns such as like #1/#2#3[#4] for example.

While I was at it 1.2 added \numexpr parsing of the N, which earlier was restricted to be only explicit digits. I allowed [] with empty N, but the way I did it in 1.2 with \the\numexpr 0#1 was buggy, as it did not allow #1 to be a \count for example or itself a \numexpr (although such inputs were not previously allowed, I later turned out to use them in the code itself, e.g. the float factorial of version 1.2f). The better way would be \the\numexpr#1+\xint\_c\_ but 1.2f finally does only \the\numexpr #1 and #1 is not allowed to be empty.

The 1.2 \XINT\_frac\_gen had two locations with such a problematic \numexpr 0#1 which I replaced for 1.2f with \numexpr#1+\xint\_c\_.

Regarding calling the macro with an argument A[<expression>], a / in the expression must be suitably hidden for example in \firstofone type constructs.

Note: when the numerator is found to be zero \XINT\_inFrac \*always\* returns {0}{0}{1}. This behaviour must not change because 1.2g \xintFloat and XINTinFloat (for example) rely upon it: if the denominator on output is not 1, then \xintFloat assumes that the numerator is not zero.

As described in the manual, if the input contains a (final) [N] part, it is assumed that it is in the shape A[N] or A/B[N] with A (and B) not containing neither decimal mark nor scientific part, moreover B must be positive and A have at most one minus sign (and no plus sign). Else there will be errors, for example -0/2[0] would not be recognized as being zero at this stage and this could cause issues afterwards. When there is no ending [N] part, both numerator and denominator will be parsed for the more general format allowing decimal digits and scientific part and possibly multiple leading signs.

1.21 fixes frailty of \XINT\_infrac (hence basically of all xintfrac macros) respective to non terminated \numexpr input: \xintRaw{\the\numexpr} for example. The issue was that \numexpr sees the / and expands what's next. But even \numexpr 1// for example creates an error, and to my mind this is a defect of \numexpr. It should be able to trace back and see that / was used as delimiter not as operator. Anyway, I thus fixed this problem belatedly here regarding \XINT\_infrac.

```

## 8.7 \XINT\_frac\_gen

Extended in 1.07 to recognize and accept scientific notation both at the numerator and (possible) denominator. Only a lowercase e will do here, but uppercase E is possible within an *xintexpr..relax*.

Completely rewritten for 1.2 2015/10/10. The parsing handles inputs such as *\A.\Be\C/\D.\Ee\F* where each of *\A*, *\B*, *\D*, and *\E* may need f-expansion and *\C* and *\F* will end up in *\numexpr*.

1.2f corrects an issue to allow *\C* and *\F* to be *\count* variable (or expressions with *\numexpr*): 1.2 did a bad *\numexpr0#1* which allowed only explicit digits for expanded #1.

```

## 8.8 *XINT\_factortens*

This is the core macro for *\xintREZ*. To be used as *\romannumeral0\XINT\_factortens{...}*. Output is A.N. (formerly {A}{N}) where A is the integer stripped from trailing zeroes and N is the number of removed zeroes. Only for positive strict integers!

Completely rewritten at 1.3a to replace a double *\xintReverseOrder* by a direct *\numexpr* governed expansion to the end and back, à la 1.2. I should comment more... and perhaps improve again in future.

Testing shows significant gain at 100 digits or more.

```

## 8.13 \xintSPRaw

This private macro was for internal usage by \xinttheexpr. It got moved here at 1.4 and is not used anymore by the package.

It checks if input has a [N] part, if yes uses \xintPRaw, else simply lets the input pass through as is.

```

433 \def\xINT_spraw_p #1[\W]{\xintpraw {#1}}%

```

## 8.14 \xintFracToSci

1.4, refactored and much simplified at 1.4e.

It only needs to be x-expandable, and indeed the implementation here is only x-expandable.

(2021/04/13) the user documentation was really deplorable, I have tried to improve it and in the process tried to remember what this macro was supposed to do, and improved comments here, also lamentable.

At 1.4e-dev this became provisionally basically like defunct *\xintSPRaw*, but doing less parsing at it does not go to *\xintPRaw* with its *\XINT\_infrac* induced overhead. Previous 1.4b *\xintFracToSci* was much complicated from having to allow fixed point notation on input and scientific notation with a catcode 12 "e". Refactoring of *\xintiexpr* has removed these constraints. Now:

Input: A, A/B, A[N], A/B[N]

Output: AeN/B with special cases:

    0 if input gives a zero value

    /B is skipped in output if B=1 in input

    eN is skipped in output if N=0 in input

0[N] when N not zero is possible as input, but 0/B currently not I think, and -0 for example never arises as one is guaranteed that A is in strict integer format.

(2021/05/05) Finally for 1.4e release I modify. This is breaking change for all *\xinteval* output in case of scientific notation: it will not be with an integer mantissa, but in regular scientific notation, using the same rules as *\xintPFloat*.

Of course there will be no float rounding applied! Also, as [0] will always or almost always be present from an *\xinteval*, we want then to use integer not scientific notation. But expression contained decimal fixed point input, or uses scientific functions, then probably the N will not be zero and this will trigger usage of scientific notation in output.

Implementing these changes sort of ruin our previous efforts to minimize grabbing the argument, but well. So the rules now are

Input: A, A/B, A[N], A/B[N]

Output: A, A/B, A if N=0, A/B if N=0

If N is not zero, scientific notation like *\xintPFloat*, i.e. behaviour like *\xintfloateval* apart from the rounding to Digits. In particular trailing zeros are trimmed.

The zero gives 0, except in A[N] and A/B[N] cases, it may give 0.0

As a result of these last minute 1.4e changes, the *\xintFracToSci* is removed.

```

## 8.24 \xintTeXfromSci

*1.4g. The main problem is how to name this and related macros.*

*I use \expanded here, as \xintFracToSci is not f-expandable. But why do I bother with the external \expanded?*

*Some complications as I want this to be usable on output of \xintFracToSci hence need to handle the case of a /B. After some hesitations I ended with the following which looks reasonable:*

- if no scientific part, use \frac (or \over) for A/B
- if scientific part, postfix /B as \cdot B^{-1}

```

### 8.33 \xintTFRac

1.09i, for *frac* in *xintexpr*. And *\xintFrac* is already assigned. T for truncation. However, potentially not very efficient with numbers in scientific notations, with big exponents. Will have to think it again some day. I hesitated how to call the macro. Same convention as in maple, but some people reserve fractional part to *x* - *floor(x)*. Also, not clear if I had to make it negative (or

zero) if  $x < 0$ , or rather always positive. There should be in fact such a thing for each rounding function, *trunc*, *round*, *floor*, *ceil*.

```

### 8.34 \xintTrunc, \xintiTrunc

This of course has a long history. Only showing here some comments.

1.2i release notes: ever since its inception this macro was stupid for a decimal input: it did not handle it separately from the general fraction case  $A/B[N]$  with  $B>1$ , hence ended up doing divisions by powers of ten. But this meant that nesting *\xintTrunc* with itself was very inefficient.

1.2i version is better. However it still handles  $B>1$ ,  $N<0$  via adding zeros to B and dividing with this extended B. A possibly more efficient approach is implemented in *\xintXTrunc*, but its logic is more complicated, the code is quite longer and making it f-expandable would not shorten it... I decided for the time being to not complicate things here.

1.4a (2020/02/18) adds handling of a negative first argument.

Zero input still gives single digit 0 output as I did not want to complicate the code. But if quantization gives 0, the exponent [D] will be there. Well actually eD because of problem that sign of original is preserved in output so we can have -0 and I can not use -0[D] notation as it is not legal for strict format. So I will use -0eD hence eD generally even though this means so slight suboptimality for *trunc()* function in *\xintexpr*.

The idea to give a meaning to negative D (in the context of optional argument to *\xintexpr*) was suggested a long time ago by Kpym (October 20, 2015). His suggestion was then to treat it as positive D but trim trailing zeroes. But since then, there is *\xintDecToString* which can be combined with *\xintREZ*, and I feel matters of formatting output require a whole module (or rather use existing third-party tools), and I decided to opt rather for an operation similar as the *quantize()* of Python Decimal module. I.e. we truncate (or round) to an integer multiple of a given power of 10.

Other reason to decide to do this is that it looks as if I don't even need to understand the original code to hack into its ending via *\XINT\_trunc\_G* or *\XINT\_itrunc\_G*. For the latter it looks as if logically I simply have to do nothing. For the former I simply have to add some eD postfix.

### 8.35 \xintTTrunc

1.1. Modified in 1.2i, it does simply *\xintiTrunc0* with no shortcut (the latter having been modified)

```

1020 \def\xintTTrunc {\romannumeral0\xintttrunc }%
1021 \def\xintttrunc {\xintitrunc\xint_c_}%

```

### 8.36 \xintNum

```
1022 \let\xintnum \xintttrunc
```

### 8.37 \xintRound, \xintiRound

Modified in 1.2i.

It benefits first of all from the faster *\xintTrunc*, particularly when the input is already a decimal number (denominator B=1).

And the rounding is now done in 1.2 style (with much delay, sorry), like of the rewritten *\xintInc* and *\xintDec*.

At 1.4a, first argument can be negative. This is handled at *\XINT\_trunc\_G*.

### 8.38 \xintXTrunc

1.09j [2014/01/06] This is completely expandable but not f-expandable. Rewritten for 1.2i (2016/12/04):

- no more use of *\xintiloop* from *xinttools.sty* (replaced by *\xintreplicate...* from *xintkernel.sty*),

- no more use in  $0>N>-D$  case of a dummy control sequence name via `\csname...\endcsname`
- handles better the case of an input already a decimal number

Need to transfer code comments into public dtx.

```

## 8.54 `\xintDivMod`

1.2p. `\xintDivMod{q1}{q2}` outputs  $\{ \text{floor}(q1/q2) \} \{ q1 - q2 * \text{floor}(q1/q2) \}$ . Attention that it relies on `\xintiiE{x}{e}` returning *x* if *e* < 0.

Modified (like `\xintAdd` and `\xintSub`) at 1.3 to use a l.c.m for final denominator of the "mod" part.

```

## 8.59 \xintMaxof

1.21 protects `\xintMaxof` against items with non terminated `\the\numexpr` expressions.

1.4 renders the macro compatible with an empty argument and it also defines an accessor `\XINT_Maxof` suitable for `xintexpr` usage (formerly `xintexpr` had its own macro handling comma separated values, but it changed internal representation at 1.4).

## 8.67 \xintGCD

**1.4 (2020/01/31).** They replace the former *xintgcd* macros of the same names which truncated to integers their arguments. Fraction-producing *gcd()* and *lcm()* functions were available since [1.3d](#) *xintexpr*, with non-public support macros handling comma separated values.

**1.4d (2021/03/29).** Somewhat strangely *\xintGCD* was formerly *\xintGCDof* used with only two arguments, as the latter directly implemented a fractionl gcd algorithm using *\xintMod* repeatedly for two arguments.

Now *\xintGCD* contains the pairwise gcd routine and *\xintGCDof* is only a wrapper. And the pairwise gcd is reduced to integer-only computations to hopefully reduce fraction overhead.

Each input is filtered via *\xintPIrr* and *\xintREZ* to reduce size of maniuplate integers in algebra.

But hesitation about applying *\xintPIrr* to output, and/or *\xintREZ*. (as it is applied on input).

But as the code is now used for frational lcm's we actually need to do some reduction of output else lcm's of integers will not be necessarily printed by *\xinteval* as integers.

Well finally I apply *\xintIrr* (but not *\xintREZ* to output). Hesitations here (thinking of inputs with large [n] parts, the output will have many zeros). So I do this only for the user macro but the core routine as used by *\xintGCDof* will not do it.

Also at [1.4d](#) the code uses *\expanded*.

## 8.68 \xintGCDof

**1.4 (2020/01/31).** This inherits from former non public *xintexpr* macro called *\xintGCDof:csv*, which handled comma separated items.

It handles fractions presented as braced items and is the support macro for the *gcd()* function in *\xintexpr* and *\xintfloatexpr*. The support macro for the *gcd()* function in *\xintiiexpr* is *\xintiiGCDof*, from *xint*.

An empty input is allowed but I have some hesitations on the return value of 1.

**1.4d (2021/03/29).** Sadly the 1.4 version had multiple problems:

- broken if first argument vanished,
- broken if some argument was not in strict format, for example had leading chains of signs or zeros (*\xintGCDof{2}{03}*). This bug originates in the fact the original macro was used only in *xintexpr* sanitized context.

Also, output is now always an irreducible fraction (ending with [0]).

## 8.71 Floating point macros

For a long time the float routines dating back to releases 1.07/1.08a (May-June 2013) were not modified.

Since 1.2f (March 2016) the four operations first round their arguments to *\xinttheDigits*-floats (or P-floats), not (*\xinttheDigits*+2)-floats or (P+2)-floats as was the case with earlier releases.

The four operations addition, subtraction, multiplication, division have always produced the correct rounding of the theoretical exact value to P or *\xinttheDigits* digits when the inputs are decimal numbers with at most P digits, and arbitrary decimal exponent part.

From 1.08a to 1.2j, *\xintFloat* (and *\XINTinFloat* which is used to parse inputs to other float macros) handled a fractional input A/B via an initial replacement to A'/B' where A' and B' were A and B truncated to Q+2 digits (where asked-for precision is Q), and then they correctly rounded A' / B' to Q digits. But this meant that this rounding of the input could differ (by up to one unit in the last place) from the correct rounding of the original A/B to the asked-for number of digits (which until 1.2f in uses as auxiliary to the macros for the basic operations was 2 more than the prevailing precision).

Since 1.2k all inputs are correctly rounded to the asked-for number of digits (this was, I think, the case in the 1.07 release -- there are no code comments -- but was, afaicr, not very efficiently done, and this is why the 1.08a release opted for truncation of the numerator and denominator.)

Notice that in float expressions, the / is treated as operator, hence the above discussion makes a difference only for the special input form *qfloat(A/B)* or for an *\xintexpr A/B\relax* embedded in the float expression, with A or B having more digits than the prevailing float precision.

Internally there is no inner representation of P-floats as such !!!!!

The input parser will again compute the length of the mantissa on each use !!! This is obviously something that must be improved upon before implementation of higher functions.

Currently, special tricks are used to quickly recognize inputs having no denominators, or fractions whose numerators and denominators are not too long compared to the target precision P, and in particular P-floats or quotients of two such.

Another long-standing issue is that float multiplication will first compute the 2P or 2P-2 digits of the exact product, and then round it to P digits. This is sub-optimal for large P particularly as the multiplication algorithm is basically the schoolbook one, hence worse than quadratic in the TeX implementation which has extra cost of fetching long sequences of tokens.

Changes at 1.4e (done 2021/04/15; undone 2021/04/29)

Macros named *\XINTinFloat<name>* are not public user-level but were designed a long time ago for *\xintfloatexpr* context as a very preliminary step towards attempting to preserve some internal format, here A[N] type.

When <name> is lowercased it means it needs a *\romannumeral0* trigger (*\XINTinfloatS* keeps an uppercase S).

Most were coded to check for an optional argument [D], and to use D=*\XINTdigits* in its place if absent but it turned out only *\XINTinfloatpow*, *\XINTinfloatmul*, *\XINTinfloatadd* were actually used with an optional argument and this happened only in macros from the very old *xintseries.sty*, so I changed all of them to not check for optional argument [D] anymore, keeping only some private interface for the *xintseries.sty* use case. Some required being used with [D], some still had names ending in "digits" indicating they would use *\XINTdigits* always.

Indeed basically all algebra is done "exactly" and the [D] governs rules of float-rounding on input and output.

During development of 1.4e we fleetingly experimented with letting the value used in place of D be *\XINTdigitsx* to 1.4e, i.e. *\XINTdigits* with guard digits, a situation which was motivated

by the implementation of trigonometrical functions at high level, i.e. using `\xintdeffloatfunc` which had no mechanism to make intermediate calculations with guard digits.

Simply doing everything "as is" but with 2 guard digits proved very good (surprisingly efficient, even) to the trigonometrical functions. However using them systematically raises many issues (for example, the correct rounding at P digits is destroyed if we obtain it a D=P+2 then round from P+2 to P digits so we definitely can not do this as default, so some interface is needed to define intermediate functions only using such guard digits and keeping them in their output).

Finally, an approach limited to the `xinttrig.sty` scope was used and I removed all `\XINTdigitsx` related matters from 1.4e. But this left some modifications of the interfaces of the "float" macros here which this list tries to document, mainly for the author's benefit.

Macros always using `\XINTdigits` and now not allowing [P] option

```
\XINTinFloatAdd
\XINTinFloatSub
\XINTinFloatMul
\XINTinFloatSqr
\XINTinFloatInv
\XINTinFloatDiv
\XINTinFloatPow
\XINTinFloatPower
\XINTinFloatPFactorial
\XINTinFloatBinomial
```

Macros which already did not allow [P] option prior to 1.4e refactoring

```
\XINTinFloatFrac (renamed from \XINTinFloatFracdigits)
\XINTinFloatE
\XINTinFloatMod
\XINTinFloatDivFloor
\XINTinFloatDivMod
```

Macros requiring a [P]. Some of the "\_wopt" named macros are renamings of macros formerly requiring [P].

```
\XINTinFloat
\XINTinFloatS
\XINTfloatLogTen
\XINTinRandomFloatS (this one has only the [P] mandatory argument)
\XINTinFloatFac
\XINTinFloatSqrt
\XINTinFloatAdd_wopt, \XINTinfloatadd_wopt
\XINTinFloatSub_wopt, \XINTinfloatsub_wopt
\XINTinFloatMul_wopt, \XINTinfloatmul_wopt
\XINTinFloatSqr_wopt
\XINTinfloatpow_wopt (not FloatPow)
\XINTinFloatDiv_wopt
\XINTinFloatInv_wopt
```

Specially named macros indicating usage of `\XINTdigits`

```
\XINTinFloatdigits
\XINTinFloatSdigits
\XINTfloatLogTendigits
\XINTinRandomFloatSdigits
\XINTinFloatFacdigits
\XINTinFloatSqrtdigits
```

## 8.72 \xintDigits, \xintSetDigits

1.3f allows `\xintDigits=` in place of `\xintDigits:=` syntax. It defines `\xintDigits*[:]=` which reloads *xinttrig.sty*. Perhaps this should be default, well.

During 1.4e development I added an interface for guard digits, but I decided to drop inclusion from 1.4e release because there were pending issues both in documentation and functionalities for which I did not have time left.

1.4e fixes the issue that `\xinttheDigits` could not be used in the right hand side of `\xintDigits[*][:]=...` or inside the argument to `\xintSetDigits`.

```
2089 \mathchardef\XINTdigits 16
2090 \chardef\XINTguardddigits 0
2091 \def\xinttheDigits {\number\XINTdigits}%
2092 %\def\xinttheGuardDigits{\number\XINTguardddigits}%
2093 \def\xinttheGuardDigits{0}%
2094 \def\xintDigits #1={\afterassignment\xintDigits_i\mathchardef\XINT_digits=}%
2095 \def\xintDigits_i#1%
2096 {%
2097     \let\XINTdigits\XINT_digits
2098 }%
2099 \def\xintSetDigits #1%
2100 {%
2101     \mathchardef\XINT_digits=\numexpr#1\relax
2102     \let\XINTdigits=\XINT_digits
2103 }%
```

## 8.73 \xintFloat

1.2f and 1.2g brought some refactoring which resulted in faster treatment of decimal inputs. 1.2i dropped use of some old routines dating back to pre 1.2 era in favor of more modern `\xintDSRr` for rounding. Then 1.2k improves again the handling of denominators B with few digits.

But the main change with 1.2k is a complete rewrite of the B>1 case in order to achieve again correct rounding in all cases.

The original version from 1.07 (May 2013) computed the exact rounding to P digits for all inputs. But from 1.08 on (June 2013), the macro handled A/B input by first truncating both A and B to at most P+2 digits. This meant that decimal input (arbitrarily long, with scientific part) was correctly rounded, but in case of fractional input there could be up to 0.6 unit in the last place difference of the produced rounding to the input, hence the output could differ from the correct rounding.

Example with 16 digits (the default): `\xintFloat {1/17597472569900621233}`

with `xintfrac 1.07`: 5.682634230727187e-20

with `xintfrac 1.08b--1.2j`: 5.682634230727188e-20

with `xintfrac 1.2k`: 5.682634230727187e-20

The exact value is 5.682634230727187499924124...e-20, showing that 1.07 and 1.2k produce the correct rounding.

Currently the code ends in a more costly branch in about 1 case among 500, where it does some extra operations (a multiplication in particular). There is a free parameter delta (here set at 4), I have yet to make some numerical explorations, to see if it could be favorable to set it to a higher value (with delta=5, there is only 1 exceptional case in 5000, etc...).

I have always hesitated about the policy of printing 10.00...0 in case of rounding upwards to the next power of ten. Already since 1.2f `\XINTinFloat` always produced a mantissa with exactly P digits (except for the zero value). Starting with 1.2k, `\xintFloat` drops this habit of printing 10.00..0 in such cases. Side note: the rounding-up detection worked when the input A/B was with numerator A and denominator B having each less than P+2 digits, or with B=1, else, it could happen

that the output was a power of ten but not detected to be a rounding up of the original fraction. The value was ok, but printed  $1.0\dots 0eN$  with  $P-1$  zeroes, not  $10.0\dots 0e(N-1)$ .

I decided it was not worth the effort to enhance the algorithm to detect with 100% fiability all cases of rounding up to next power of ten, hence 1.2k dropped this.

To avoid duplication of code, and any extra burden on *\XINTinFloat*, which is the macro used internally by the float macros for parsing their inputs, we simply make now *\xintFloat* a wrapper of *\XINTinFloat*.

## 8.74 *\XINTinFloat*, *\XINTinFloatS*, *\XINTiLogTen*

This routine is like *\xintFloat* but produces an output of the shape  $A[N]$  which is then parsed faster as input to other float macros. Float operations in *\xintfloatexpr\dots\relax* use internally this format.

It must be used in form *\XINTinFloat[P]{f}*: the optional [P] is mandatory.

Since 1.2f, the mantissa always has exactly P digits even in case of rounding up to next power of ten. This simplifies other routines.

(but the zero value must always be checked for, as it outputs 0[0])

1.2g added a variant *\XINTinFloatS* which, in case of decimal input with less than the asked for precision P will not add extra zeros to the mantissa. For example it may output 2[0] even if P=500, rather than the canonical representation 200...000[-499]. This is how *\xintFloatMul* and *\xintFloatDiv* parse their inputs, which speeds-up follow-up processing. But *\xintFloatAdd* and *\xintFloatSub* still use *\XINTinFloat* for parsing their inputs; anyway this will have to be changed again when inner structure will carry upfront at least the length of mantissa as data.

Each time *\XINTinFloat* is called it at least computes a length. Naturally if we had some format for floats that would be dispensed of...

something like <letterP><length of mantissa>.mantissa.exponent, etc... not yet.

Since 1.2k, *\XINTinFloat* always correctly rounds its argument, even if it is a fraction with very big numerator and denominator. See the discussion of *\xintFloat*.

1.3e adds *\XINTfloatiLogTen*.

## 8.75 \xintPFloat, \xintPFloatE

*xint* has not yet incorporated a general formatter as it was not a priority during development and external solutions exist (I did not check for a while but I think LaTeX3 has implemented a general formatter in the `\printf` or Python ".format" spirit)

But when one starts using really the package, especially in an interactive way (*xintsession 2021*), one needs the default output to be as nice as possible.

The `\xintPFloat` macro was added at 1.1 as a "prettifying printer" for floats, basically influenced by Maple.

The rules were:

0. The input is float-rounded to either Digits or the optional argument
  1. zero is printed as "0."
  2.  $x.yz...eK$  is printed "as is" if  $K > 5$  or  $K < -5$ .
  3. if  $-5 \leq K \leq 5$ , fixed point decimal notation is used.
  4. in cases 2. and 3., no trimming of trailing zeroes.
- 1.4b added `\xintPFloatE` to customize whether to use e or E.

1.4e, with some hesitation, decided to make a breaking change and to modify the behaviour.

The new rules:

0. The input is float-rounded to either Digits or the optional argument
1. zero is printed as 0.0
2.  $x.yz...eK$  is printed in decimal fixed point if  $-4 \leq K \leq +5$  (notice the change, formerly  $K = -5$  used fixed point notation in output) else it is printed in scientific notation
3. trailing zeros of the mantissa are trimmed always
4. in case of decimal fixed point for an integer, there is a trailing ".0"
5. in case of scientific notation with a one-digit trimmed mantissa there is an added ".0" too

Further, `\xintPFloatE` can now grab the scientific exponent K which is presented to it as explicit tokens (digit tokens, at least one, and an optional minus sign) delimited by a dot. It is thus now possible to customize at will for example adding a + sign in case of positive scientific exponent.

The macro must be f-expandable.

## 8.76 *\XINTinFloatFrac*

1.09i, for *frac* function in *\xintfloatexpr*. This version computes exactly from the input the fractional part and then only converts it into a float with the asked-for number of digits. I will have to think it again some day, certainly.

1.1 removes optional argument for which there was anyhow no interface, for technical reasons having to do with *\xintNewExpr*.

1.1a renames the macro as *\XINTinFloatFracdigits* (from *\XINTinFloatFrac*) to be synchronous with the *\XINTinFloatSqrt* and *\XINTinFloat* habits related to *\xintNewExpr* context and issues with macro names.

Note to myself: I still have to rethink the whole thing about what is the best to do, the initial way of going through *\xinttfrac* was just a first implementation.

1.4e renames it back to *\XINTinFloatFrac* because of all such similarly named macros also using *\XINTdigits* forcedly.

```

```

## 8.77 *\xintFloatAdd*, *\XINTinFloatAdd*

First included in release 1.07.

1.09ka improved a bit the efficiency. However the *add*, *sub*, *mul*, *div* routines were provisory and supposed to be revised soon.

Which didn't happen until 1.2f. Now, the inputs are first rounded to P digits, not P+2 as earlier.

See general introduction for important changes at 1.4e relative to the *\XINTinFloat<name>* macros.

## 8.79 **\xintFloatMul**, **\XINTinFloatMul**

1.07.

Starting with 1.2f the arguments are rounded to the target precision P not P+2.

1.2g handles the inputs via `\XINTinFloatS` which will be more efficient when the precision is large and the input is for example a small constant like 2.

1.2k does a micro improvement to the way the macro passes over control to its output routine (former version used a higher level `\xintE` causing some extra un-needed processing with two calls to `\XINT_infrac` where one was amply enough).

```

2520 \def\xintFloatMul {\romannumeral0\xintfloatmul}%

```

## 8.80 **\xintFloatSqr**, **\XINTinFloatSqr**

Added only at 1.4e, strangely *\xintFloatSqr* had never been defined so far.

An *\XINTinFloatSqr*{#1} was defined in *xintexpr.sty* directly as *\XINTinFloatMul[\XINTdigits]{#1}{#1}*, to support the *sqr()* function. The {#1}{#1} causes no problem as #1 in this context is always pre-expanded so we don't need to worry about this, and the *\xintdeffloatfunc* mechanism should hopefully take care to add the needed argument pre-expansion if need be.

Anyway let's do this finally properly here.

```

2551 \def\xintFloatSqr {\romannumeral0\xintfloatsqr}%
2552 \def\xintfloatsqr #1{\XINT_flsqr_chkopt \xintfloat #1\xint:}%

2575 \def\XINTinFloatSqr_wopt[#1]#2{\XINTinFloatS[#1]{\expandafter\XINT_FL_sqr_a\romannumeral0\XINTinfloatS[#1]{#2}}%

```

## 8.81 **\XINTinFloatInv**

Added belatedly at 1.3e, to support *inv()* function. We use Short output, for rare *inv(\xintexpr 1/3\relax)* case. I need to think the whole thing out at some later date.

```
2576 \def\xINTinFloatInv#1{\XINTinFloatS[\XINTdigits]{\xintInv{#1}}}%
2577 \def\xINTinFloatInv_wopt[#1]#2{\XINTinFloatS[#1]{\xintInv{#2}}}%
```

## 8.82 \xintFloatDiv, \XINTinFloatDiv

1.07.

Starting with 1.2f the arguments are rounded to the target precision P not P+2.

1.2g handles the inputs via \XINTinFloatS which will be more efficient when the precision is large and the input is for example a small constant like 2.

The actual rounding of the quotient is handled via \xintfloat (or \XINTinfloatS).

1.2k does the same kind of improvement in \XINT\_FL\_div\_b as for multiplication: earlier code was unnecessarily high level.

```
2578 \def\xintFloatDiv {\romannumeral0\xintfloatdiv}%
2579 \def\xintfloatdiv #1{\XINT_fldiv_chkopt \xintfloat #1\xint:}%
2580 \def\xINTinFloatDiv{\romannumeral0\xINTinfloatdiv}%
2581 \def\xINTinfloatdiv{\XINT_fldiv_opt_a\XINTdigits.\XINTinfloatS}%
2582 \def\xINTinFloatDiv_wopt[#1]{\romannumeral0\XINT_fldiv_opt_a#1.\XINTinfloatS}%
2583 \def\xINT_fldiv_chkopt #1#2%
2584 {%
2585     \ifx [#2\expandafter\XINT_fldiv_opt
2586         \else\expandafter\XINT_fldiv_noopt
2587     \fi #1#2%
2588 }%
```

1.4g adds here intercept of second argument being zero, else a low level error will arise at later stage from the the fall-back value returned by core iidivision being 0 and not having expected number of digits at \XINT\_infloat\_Qq and split from left returning some empty value breaking the \ifnum test in \XINT\_infloat\_Rq.

```
2589 \def\xINT_fldiv_noopt #1#2\xint:#3%
2590 {%

2615 \def\XINT_FL_div_b #1[#2]{#1e#2}%

```

## 8.83 \xintFloatPow, \XINTinFloatPow

1.07: initial version. 1.09j has re-organized the core loop.

2015/12/07. I have hesitated to map  $\wedge$  in expressions to *\xintFloatPow* rather than *\xintFloatPower*. But for 1.234567890123456 to the power 2145678912 with P=16, using Pow rather than Power seems to bring only about 5% gain.

This routine requires the exponent x to be compatible with *\numexpr* parsing.

1.2f has rewritten the code for better efficiency. Also, now the argument A for  $A^x$  is first rounded to P digits before switching to the increased working precision (which depends upon x).

```

This ending is common with *\xintFloatPower*.

In the case of negative exponent we need to inverse the Q-digits mantissa. This requires no special attention now as 1.2k's *\xintFloat* does correct rounding of fractions hence it is easy to bound the total error. It can be checked that the algorithm after final rounding to the target precision computes a value Z whose distance to the exact theoretical will be less than 0.52 ulp(Z) (and worst cases can only be slightly worse than 0.51 ulp(Z)).

In the case of the half-integer exponent (only via the expression interface,) the computation (which proceeds via *\XINTinFloatPowerH*) ends with a square root. This square root extraction is done with 3 guard digits (the power operations were done with more.) Then the value is rounded to the target precision. There is thus this rounding to 3 guard digits (in the case of negative exponent the reciprocal is computed before the square-root), then the square root is (computed with exact rounding for these 3 guard digits), and then there is the final rounding of this to the target precision. The total error (for positive as well as negative exponent) has been estimated to at worst possibly exceed slightly 0.5125 ulp(Z), and at any rate it is less than 0.52 ulp(Z).

## 8.84 *\xintFloatPower*, *\XINTinFloatPower*

1.07. The core loop has been re-organized in 1.09j for some slight efficiency gain. The exponent B is given to *\xintNum*. The  $\wedge$  in expressions is mapped to this routine.

Same modifications as in *\xintFloatPow* for 1.2f.

1.2f *\XINTinFloatPowerH* (now moved to *xintlog*, and renamed). It truncated the exponent to an integer of half-integer, and in the latter case use Square-root extraction. At 1.2k this was improved as 1.2f stupidly rounded to Digits before, not after the square root extraction, 1.2k kept 3 guard digits for this last step. And the initial step was changed to a rounding rather than truncating.

Until 1.4e this *\XINTinFloatPowerH* was the macro for  $a^b$  in expressions, but of course it behaved strangely for b not an integer or an half-integer! At 1.4e, the non-integer, non-half-integer exponents will be handled via *log10()* and *pow10()* support macros, see *xintlog*. The code has now been relocated there.

## 8.85 `\xintFloatFac`, `\XINTFloatFac`

Done at 1.2.

At 1.3e `\XINTinFloatFac` uses `\XINTinFloatS` for output.

1.4e adds some overhead for individual evaluations in float context as it obeys the guard digits for the default target precision. It is a waste for individual evaluation of one factorial...

```

```

Computations are done with Q blocks of eight digits. When a multiplication has a carry, hence creates Q+1 blocks, the least significant one is dropped. The goal is to compute an approximate value X' to the exact value X, such that the final relative error  $(X-X')/X$  will be at most  $10^{-(P-1)}$  with P the desired precision. Then, when we round X' to X'' with P significant digits, we can prove that the absolute error  $|X-X''|$  is bounded (strictly) by 0.6 ulp(X''). (ulp= unit in the last (significant) place). Let N be the number of such operations, the formula for Q deduces from the previous explanations is that  $8Q$  should be at least  $P+9+k$ , with k the number of digits of N (in base 10). Note that 1.2 version used  $P+10+k$ , for 1.2f I reduced to  $P+9+k$ . Also, k should be the number of digits of the number N of multiplications done, hence for  $n \leq 10000$  we can take  $N=n/2$ , or  $N/3$ , or  $N/4$ . This is rounded above by numexpr and always an overestimate of the actual number of approximate multiplications done (the first ones are exact). (vérifier ce que je raconte, j'ai la flemme là).

We then want  $\text{ceil}((P+k+n)/8)$ . Using \numexpr rounding division (ARRRRRGHHHHH), if m is a positive integer,  $\text{ceil}(m/8)$  can be computed as  $(m+3)/8$ . Thus with  $m=P+10+k$ , this gives  $Q<-(P+13+k)/8$ .

The routine actually computes  $8(Q-1)$  for use in `\XINT_FL_fac_addzeros`.

With 1.2f the formula is  $m=P+9+k$ ,  $Q<-(P+12+k)/8$ , and we use now  $4=12-8$  rather than the earlier  $5=13-8$ . Whatever happens, the value computed in `\XINT_FL_fac_increaseP` is at least 8. There will always be an extra block.

Note: with `Digits:=32`; Maple gives for 200!:

```
> factorial(200.);
```

375

0.78865786736479050355236321393218 10

My 1.2f routine (and also 1.2) outputs:

7.8865786736479050355236321393219e374

and this is the correct rounding because for 40 digits it computes

7.886578673647905035523632139321850622951e374

Maple's result (contrarily to *xint*) is thus not the correct rounding but still it is less than 0.6 ulp wrong.

This is the crucial ending. I note that I used here an `\ifnum` test rather than the `gob_til_eightzeroes` thing. Actually for eight digits there is much less difference than for only four.

The "carry" situation is marked by a final `!-1` rather than `!-2` for no-carry. (a `\numexpr` must be stopped, and leaving a `-` as delimiter is good as it will not arise earlier.)

## 8.86 `\xintFloatPFactorial`, `\XINTinFloatPFactorial`

2015/11/29 for 1.2f. Partial factorial `pfactorial(a,b)=(a+1)...b`, only for non-negative integers with  $a \leq b < 10^8$ .

1.2h (2016/11/20) now avoids raising `\xintError:OutOfRangePFac` if the condition  $0 \leq a \leq b < 10^8$  is violated. Same as for `\xintiiPFactorial`.

1.4e extends the precision in floating point context adding some overhead but well.

```

See the comments for `\XINT_FL_pfac_increaseP`. Case of  $b=a+1$  should be filtered out perhaps. We only needed here to copy the `\xintPFactorial` macros and re-use `\XINT_FL_fac_mul`/`\XINT_FL_fac_out`. Had to modify a bit `\XINT_FL_pfac_addzeroes`. We can enter here directly with `#3` equal to specify the precision (the calculated value before final rounding has a relative error less than  $\#3.10^{-\#4-1}$ ), and `#5` would hold the macro doing the final rounding (or truncating, if I make a `FloatTrunc` available) to a given number of digits, possibly not `#4`. By default the `#3` is 1, but `FloatBinomial` calls it with `#3=4`.

## 8.87 `\xintFloatBinomial`, `\XINTinFloatBinomial`

1.2f. We compute  $\text{binomial}(x,y)$  as  $\text{pfac}(x-y,x)/y!$ , where the numerator and denominator are computed with a relative error at most  $4.10^{-P-2}$ , then rounded (once I have a float truncation, I will use truncation rather) to  $P+3$  digits, and finally the quotient is correctly rounded to  $P$  digits. This will guarantee that the exact value  $X$  differs from the computed one  $Y$  by at most  $0.6 \text{ulp}(Y)$ . (2015/12/01).

2016/11/19 for 1.2h. As for `\xintiiBinomial`, hard to understand why last year I coded this to raise an error if  $y < 0$  or  $y > x$  ! The question of the Gamma function is for another occasion, here  $x$  and  $y$  must be (small) integers.

1.4e: same remarks as for factorial and partial factorial about added overhead due to extra guard digits.

## 8.88 **\xintFloatSqrt**, **\XINTinFloatSqrt**

First done for 1.08.

The float version was developed at the same time as the integer one and even a bit earlier. As a result the integer variant had some sub-optimal parts. Anyway, for 1.2f I have rewritten the integer variant, and the float variant delegates all preparatory work for it until the last step. In particular the very low precisions are not penalized anymore from doing computations for at least 17 or 18 digits. Both the large and small precisions give quite shorter computation times.

Also, after examining more closely the achieved precision I decided to extend the float version in order for it to obtain the correct rounding (for inputs already of at most P digits with P the precision) of the theoretical exact value.

Beyond about 500 digits of precision the efficiency decreases swiftly, as is the case generally speaking with *xintcore/xint/xintfrac* arithmetic macros.

Final note: with 1.2f the input is always first rounded to P significant places.

1.4e (2021/04/15) great hesitation about what to do regarding guard digits. This will spoil the guaranteed "correct-rounding" property for individual calculations... but is interesting for precision as soon as the square root is embedded into some larger calculation. Annoying. But there is *\xintexpr* which I can left configured to use strictly *\xintDigits* in contrast to *\xintfloatexpr*. Ah ok and there will always be *\sqrt{x,\xinttheDigits}* syntax if one wants. And finally I keep *\sqrt()* acting the same in *expr* and *floatexpr*.

Attention that at 1.4e *\XINTinFloatSqrt* is defined to be used ONLY with optional argument .

```

3517         {\romannumeral0\XINTinfloat[#1]{#3}}}}%
3518 }%

```

## 8.92 \XINTinFloatDivMod

1.2p. Pour emploi dans *xintexpr*, donc je ne prends pas la peine de faire l'expansion du modulo, qui se produira dans le \csname.

Hésitation sur le quotient, faut-il l'arrondir immédiatement ? Finalement non, le produire comme un integer.

Breaking change at 1.4 as output format is not comma separated anymore. Attention also that it uses \expanded.

No time now at the time of completion of the big 1.4 rewrite of *xintexpr* to test whether code efficiency here can be improved to expand the second item of output.

```

## 8.96 \XINTinFloatdigits, \XINTinFloatSdigits

For `\xintNewExpr/\xintdeffloatfunc` matters, mainly.

```
3555 \def\XINTinFloatdigits {\XINTinFloat [\XINTdigits]}%
3556 \def\XINTinFloatSdigits{\XINTinFloatS[\XINTdigits]}%
```

## 8.97 (WIP) \XINTinRandomFloatS, \XINTinRandomFloatSdigits

### 1.3b. Support for random() function.

Thus as it is a priori only for *xintexpr* usage, it expands inside `\csname` context, but as we need to get rid of initial zeros we use `\xintRandomDigits` not `\xintXRandomDigits` (`\expanded` would have a use case here).

And anyway as we want to be able to use `random()` in `\xintdeffunc/\xintNewExpr`, it is good to have f-expandable macros, so we add the small overhead to make it f-expandable.

We don't have to be very efficient in removing leading zeroes, as there is only 10% chance for each successive one. Besides we use (current) internal storage format of the type `A[N]`, where `A` is not required to be with `\xintDigits` digits, so `N` will simply be `-\xintDigits` and needs no adjustment.

In case we use in future with #1 something else than `\xintDigits` we do the 0-(#1) construct.

I had some qualms about doing a random float like this which means that when there are leading zeros in the random digits the (virtual) mantissa ends up with trailing zeros. That did not feel right but I checked `random()` in Python (which of course uses radix 2), and indeed this is what happens there.

```
3557 \def\xINTinRandomFloatS{\romannumeral0\xINTinrandomfloatS}%
3558 \def\xINTinRandomFloatSdigits{\XINTinRandomFloatS[\XINTdigits]}%
3559 \def\xINTinrandomfloatS[#1]%
3560 {%
3561     \expandafter\xINT_inrandomfloatS\the\numexpr\xint_c_-(#1)\xint:%
3562 }%
3563 \def\xINT_inrandomfloatS-#1\xint:%

### 9.1 Catcodes, $\varepsilon$ - $\text{\TeX}$ and reload detection

The code for reload detection was initially copied from **HEIKO OBERDIEK**'s packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

## 9.5 \xintPowerSeries

The 1.03 version was very lame and created a build-up of denominators. (this was at a time \xintAdd always multiplied denominators, by the way) The Horner scheme for polynomial evaluation is used in 1.04, this cures the denominator problem and drastically improves the efficiency of the macro. Modified in 1.06 to give the indices first to a \numexpr rather than expanding twice. I just use \the\numexpr and maintain the previous code after that. 1.08a adds the forgotten optimization following that previous change.

154 }%

```

## 9.7 \xintRationalSeries

This computes  $F(a) + \dots + F(b)$  on the basis of the value of  $F(a)$  and the ratios  $F(n)/F(n-1)$ . As in `\xintPowerSeries` we use an iterative scheme which has the great advantage to avoid denominator build-up. This makes exact computations possible with exponential type series, which would be completely inaccessible to `\xintSeries`. #1=a, #2=b, #3=F(a), #4=ratio function Modified in 1.06 to give the indices first to a `\numexpr` rather than expanding twice. I just use `\the\numexpr` and maintain the previous code after that. 1.08a adds the forgotten optimization following that previous change.

## 9.10 \xintFxPtPowerSeriesX

*a,b,coeff,x,D*

Modified in 1.06 to give the indices first to a *\numexpr* rather than expanding twice. I just use *\the\numexpr* and maintain the previous code after that. 1.08a adds the forgotten optimization following that previous change.

```

## 9.11 \xintFloatPowerSeries

1.08a. I still have to re-visit *\xintFxPtPowerSeries*; temporarily I just adapted the code to the case of floats.

Usage of new names *\XINTinfloatapow\_wopt*, *\XINTinfloatmul\_wopt*, *\XINTinfloatadd\_wopt* to track *xintfrac.sty* changes at 1.4e.

```

## 10 Package *xintcfrac* implementation

.1	Catcodes, $\varepsilon$ - $\text{\TeX}$ and reload detection . . . . .	289
.2	Package identification . . . . .	290
.3	$\backslash xintCFrac$ . . . . .	290
.4	$\backslash xintGCFrac$ . . . . .	291
.5	$\backslash xintGGCFrac$ . . . . .	293
.6	$\backslash xintGCToGCx$ . . . . .	294
.7	$\backslash xintFtoCs$ . . . . .	294
.8	$\backslash xintFtoCx$ . . . . .	295
.9	$\backslash xintFtoC$ . . . . .	296
.10	$\backslash xintFtoGC$ . . . . .	296
.11	$\backslash xintFGtoC$ . . . . .	296
.12	$\backslash xintFtoCC$ . . . . .	297
.13	$\backslash xintCtoF$ , $\backslash xintCstoF$ . . . . .	298
.14	$\backslash xintiCstoF$ . . . . .	299
.15	$\backslash xintGCToF$ . . . . .	300
.16	$\backslash xintiGCToF$ . . . . .	301
.17	$\backslash xintCtoCv$ , $\backslash xintCstoCv$ . . . . .	302
.18	$\backslash xintiCstoCv$ . . . . .	303
.19	$\backslash xintGCToCv$ . . . . .	304
.20	$\backslash xintiGCToCv$ . . . . .	305
.21	$\backslash xintFtoCv$ . . . . .	306
.22	$\backslash xintFtoCCv$ . . . . .	306
.23	$\backslash xintCntoF$ . . . . .	306
.24	$\backslash xintGCntoF$ . . . . .	307
.25	$\backslash xintCntoCs$ . . . . .	308
.26	$\backslash xintCntoGC$ . . . . .	309
.27	$\backslash xintGCntoGC$ . . . . .	309
.28	$\backslash xintCstoGC$ . . . . .	310
.29	$\backslash xintGCToGC$ . . . . .	310

The commenting is currently (2021/06/11) very sparse. Release 1.09m (2014/02/26) has modified a few things:  $\backslash xintFtoCs$  and  $\backslash xintCntoCs$  insert spaces after the commas,  $\backslash xintCstoF$  and  $\backslash xintCstoCv$  authorize spaces in the input also before the commas,  $\backslash xintCntoCs$  does not brace the produced coefficients, new macros  $\backslash xintFtoC$ ,  $\backslash xintCtoF$ ,  $\backslash xintCtoCv$ ,  $\backslash xintFGtoC$ , and  $\backslash xintGGCFrac$ .

There is partial dependency on *xinttools* due to  $\backslash xintCstoF$  and  $\backslash xintCsToCv$ .

### 10.1 Catcodes, $\varepsilon$ - $\text{\TeX}$ and reload detection

The code for reload detection was initially copied from **HEIKO OBERDIEK**'s packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

```

## 10.9 \xintFtoC

New in 1.09m: this is the same as `\xintFtoCx` with empty separator. I had temporarily during preparation of 1.09m removed braces from `\xintFtoCx`, but I recalled later why that was useful (see doc), thus let's just here do `\xintFtoCx {}`

```

## 10.17 \xintCtoCv, \xintCstoCv

1.09m uses *\xintCSVtoList* on the argument of *\xintCstoCv* to allow spaces also before the commas. The original *\xintCstoCv* code became the one of the new *\xintCtoF* dealing with a braced rather than comma separated list.

## 10.25 \xintCntoCs

Modified in 1.09m: added spaces after the commas in the produced list. Moreover the coefficients are not braced anymore. A slight induced limitation is that the macro argument should not contain some explicit comma (cf. *\XINT\_cntcs\_exit\_b*), hence *\xintCntoCs {\macro,}* with *\def\macro,#1{<stuff>}* would crash. Not a very serious limitation, I believe.

## 10.26 \xintCnToGC

Modified in 1.06 to give the N first to a \numexpr rather than expanding twice. I just use \the\numexpr and maintain the previous code after that.

1.09m maintains the braces, as the coeff are allowed to be fraction and the slash can not be naked in the GC format, contrarily to what happens in \xintCnToCs. Also the separators given to \xintGCToGCx may then fetch the coefficients as argument, as they are braced.

## 11 Package *xintexpr* implementation

This is release 1.4i of 2021/06/11.

### Contents

11.1	READ ME! Important warnings and explanations relative to the status of the code source at the time of the 1.4 release . . . . .	314
11.2	Old comments . . . . .	315
11.3	Catcodes, $\varepsilon$ - $\text{\TeX}$ and reload detection . . . . .	316
11.4	Package identification . . . . .	317
11.5	$\backslash$ xintDigits*, $\backslash$ xintSetDigits*, $\backslash$ xintreloadscilibs . . . . .	317
11.6	$\backslash$ XINTdigitsmax . . . . .	318
11.7	Support for output and transform of nested braced contents as core data type . . . . .	318
11.7.1	Bracketed list rendering with prettifying of leaves from nested braced contents . . . . .	318
11.7.2	Flattening nested braced contents . . . . .	319
11.7.3	Braced contents rendering via a $\text{\TeX}$ alignment with prettifying of leaves . . . . .	319
11.7.4	Transforming all leaves within nested braced contents . . . . .	321
11.8	Top level user $\text{\TeX}$ interface: $\backslash$ xinteval, $\backslash$ xintfloateval, $\backslash$ xintieval . . . . .	321
11.8.1	$\backslash$ xintexpr, $\backslash$ xintiexpr, $\backslash$ xintfloatexpr, $\backslash$ xintiexpr . . . . .	322
11.8.2	$\backslash$ XINT_expr_wrap, $\backslash$ XINT_iexpr_wrap, $\backslash$ XINT_fexpr_wrap . . . . .	323

11.11.1	Integral part (skipping zeroes) . . . . .	334
11.11.2	Fractional part . . . . .	336
11.11.3	Scientific notation . . . . .	337
11.11.4	Hexadecimal numbers . . . . .	338
11.11.5	$\backslash$ XINT_expr_startfunc: collecting names of functions and variables . . . . .	341
11.11.6	$\backslash$ XINT_expr_func: dispatch to variable replacement or to function execution . . . . .	341
11.12	$\backslash$ XINT_expr_op_`: launch function or pseudo-function, or evaluate variable and insert operator of multiplication in front of parenthesized contents . . . . .	342
11.13	$\backslash$ XINT_expr_op__: replace a variable by its value and then fetch next operator . . . . .	343
11.14	$\backslash$ XINT_expr_getop: fetch the next operator or closing parenthesis or end of expression . . . . .	344
11.15	Expansion spanning; opening and closing parentheses . . . . .	347
11.16	The comma as binary operator . . . . .	349
11.17	The minus as prefix operator of variable precedence level . . . . .	350
11.18	The * as Python-like «unpacking» prefix operator . . . . .	351
11.19	Infix operators . . . . .	351
11.19.1	&&,   , //, /:, +, -, *, /, ^, **, 'and', 'or', 'xor', and 'mod' . . . . .	352

11.19.2	.., ..[ and ].. for a..b and a..[b]..c syntax . . . . .	354
11.19.3	<, >, ==, <=, >=, != with Python-like chaining . . . . .	356
11.19.4	Support macros for .., ..[ and ].. . . . .	358
11.20	Square brackets [] both as a container and a Python slicer . . . . .	360
11.20.1	[...] as «oneple» constructor . . . . .	360
11.20.2	[...] brackets and : operator for NumPy-like slicing and item indexing syntax . . . . .	361
11.20.3	Macro layer implementing indexing and slicing . . . . .	363
11.21	Support for raw A/B[N] . . . . .	367
11.22	? as two-way and ?? as three-way «short-circuit» conditionals . . . . .	368
11.23	! as postfix factorial operator . . . . .	369
11.24	User defined variables . . . . .	369
11.24.1	\xintdefvar, \xintdefiivar, \xintdeffloatvar . . . . .	369
11.24.2	\xintunassignvar . . . . .	373
11.25	Support for dummy variables . . . . .	374
11.25.1	\xintnewdummy . . . . .	374
11.25.2	\xintensuredummy, \xintrestorevariable . . . . .	375
11.25.3	Checking (without expansion) that a symbolic expression contains correctly nested parentheses . . . . .	376
11.25.4	Fetching balanced expressions E1, E2 and a variable name Name from E1, Name=E2) . . . . .	377
11.25.5	Fetching a balanced expression delimited by a semi-colon . . . . .	377
11.25.6	Low-level support for omit and abort keywords, the break() function, the n++ construct and the semi-colon as used in the syntax of seq(), add(), mul(), iter(), rseq(), iterr(), rrseq(), subsm(), subsn(), ndseq(), ndmap() . . . . .	378
11.25.7	Reserved dummy variables @, @1, @2, @3, @4, @@, @@(1), ..., @@@, @@@(1), ... for recursions . . . . .	379
11.26	Pseudo-functions involving dummy variables and generating scalars or sequences . . . . .	380
11.26.1	Comments . . . . .	380
11.26.2	subs(): substitution of one variable . . . . .	382
11.26.3	subsm(): simultaneous independent substitutions . . . . .	383
11.26.4	subsn(): leaner syntax for nesting (possibly dependent) substitutions . . . . .	384
11.26.5	seq(): sequences from assigning values to a dummy variable . . . . .	386
11.26.6	iter() . . . . .	387
11.26.7	add(), mul() . . . . .	388

## 11.1 READ ME! Important warnings and explanations relative to the status of the code source at the time of the 1.4 release

At release 1.4 the *csname* encapsulation of intermediate evaluations during parsing of expressions is dropped, and *xintexpr* requires the *\expanded* primitive. This means that there is no more impact on the string pool. And as internal storage now uses simply core *\TeX{}* syntax with braces rather than comma separated items inside a *csname* dummy control sequence, it became much easier to let the [...] syntax be associated to a true internal type of «tuple» or «list».

The output of *\xintexpr* (after *\romannumeral0* or *\romannumeral-`0* triggered expansion or double expansion) is thus modified at 1.4. It now looks like this:

\XINTfstop \XINTexprprint .{{<number>}} in simplest case

\XINTfstop \XINTexprprint .{{...}}...{{...}} in general case

where ... stands for nested braces ultimately ending in {{<num. rep.>}} leaves. The <num. rep.> stands for some internal representation of numeric data. It may be empty, and currently as well as probably in future uses only catcode 12 tokens (no spaces currently).

{}{{}} corresponds (in input as in output) to []. The external TeX braces also serve as set-theoretical braces. The comma is concatenation, so for example [], [] will become {{}}{{}}, or rather {{}} if sub-unit of something else.

The associated vocabulary is explained in the user manual and we avoid too much duplication here. *xintfrac* numerical macros receiving an empty argument usually handle it as being 0, but this is not the case of the *xintcore* macros supporting *\xintiiexpr*, they usually break if exercised on some empty argument.

The above expansion result \XINTfstop \XINTexprprint .{{<num1>}}{{<num2>}}... uses only normal catcodes: the backslash, regular braces, and catcode 12 characters. Scientific notation is internally converted to raw *xintfrac* representation [N].

Additional data may be located before the dot; this is the case only for *\xintfloatexpr* currently. As *xintexpr* actually defines three parsers *\xintexpr*, *\xintiiexpr* and *\xintfloatexpr* but tries to share as much code as possible, some overhead is induced to fit all into the same mold.

\XINTfstop stops *\romannumeral-`0* (or 0) type spanned expansion, and is invariant under *\edef*, but simply disappears in typesetting context. It is thus now legal to use *\xintexpr* directly in typesetting flow.

\XINTexprprint is \protected.

The f-expansion of an *\xintexpr* <expression>*\relax* is a complete expansion, i.e. one whose result remains invariant under *\edef*. But if exposed to finitely many expansion steps (at least two) there is a «blinking» *\noexpand* upfront depending on parity of number of steps.

*\xintthe*\xintexpr <expression>*\relax* or *\xinteval{<expression>}* serve as formerly to deliver the explicit digits, or more exactly some prettifying view of the actual <internal number representation>. For example *\xintthe*\xintboolexpr will (this is tentative) use True and False in output.

Nested contents like this

{}{{1}}{{2}}{{3}}{{4}}{{5}}{{6}}}{{9}}

will get delivered using nested square brackets like that

1, [2, 3, [4, 5, 6]], 9

and as conversely *\xintexpr* 1, [2, 3, [4, 5, 6]], 9*\relax* expands to

\XINTfstop \XINTexprprint .{{1}}{{2}}{{3}}{{4}}{{5}}{{6}}}{{9}}

we obtain the gratifying result that

```
\xinteval{1, [2, 3, [4, 5, 6]], 9}
expands to
```

```
1, [2, 3, [4, 5, 6]], 9
```

See user manual for explanations on the plasticity of `\xintexpr` syntax regarding functions with multiple arguments, and the 1.4 «unpacking» Python-like `*` prefix operator.

I have suppressed (from the public dtx) many big chunks of comments. Some became obsolete and need to be updated, others are currently of value only to the author as a historical record.

ATTENTION! As the removal process itself took too much time, I ended up leaving as is many comments which are obsoleted and wrong to various degrees after the 1.4 release. Precedence levels of operators have all been doubled to make room for new constructs

Even comments added during 1.4 developement may now be obsolete because the preparation of 1.4 took a few weeks and that's enough of duration to provide the author many chances to contradict in the code what has been already commented upon.

Thus don't believe (fully) anything which is said here!

Warning: in text below and also in left-over old comments I may refer to «until» and «op» macros; due to the change of data storage at 1.4, I needed to refactor a bit the way expansion is controlled, and the situation now is mainly governed by «op», «exec», «check-» and «checkp» macros the latter three replacing the two «until\_a» and «until\_b» of former code. This allows to diminish the number of times an accumulated result will be grabbed in order to propagate expansion to its right. Formerly this was not an issue because such things were only a single token! I do not describe here how this is all articulated but it is not hard to see it from the code (the hardest thing in all such matter was in 2013 to actually write how the expansion would be initially launched because to do that one basically has to understand the mechanism in its whole and such things are not easy to develop piecemeal). Another thing to keep in mind is that operators in truth have a left precedence (i.e. the precedence they show to operators arising earlier) and a right precedence (which determines how they react to operators coming after them from the right). Only the first one is usually encapsulated in a chardef, the second one is most of the times identical to the first one and if not it is only virtual but implemented via `\ifcase` of `\ifnum` branching. A final remark is that some things are achieved by special «op» macros, which are a favorite tool to hack into the normal regular flow of things, via injection of special syntax elements. I did not rename these macros for avoiding too large git diffs, and besides the nice thing is that the 1.4 refactoring minimally had to modify them, and all hacky things using them kept on working with not a single modification. And a post-scriptum is that advanced features crucially exploit injecting sub-`\xintexpr`-essions, as all is expandable there is no real «context» (only a minimal one) which one would have to perhaps store and restore and doing this sub-expression injection is rather cheap and efficient operation.

## 11.2 Old comments

These general comments were last updated at the end of the 1.09x series in 2014. The principles remain in place to this day but refer to [CHANGES.html](#) for some significant evolutions since.

The first version was released in June 2013. I was greatly helped in this task of writing an expandable parser of infix operations by the comments provided in `13fp-parse.dtx` (in its version as available in April-May 2013). One will recognize in particular the idea of the 'until' macros; I have not looked into the actual `13fp` code beyond the very useful comments provided in its documentation.

A main worry was that my data has no a priori bound on its size; to keep the code reasonably efficient, I experimented with a technique of storing and retrieving data expandably as names of control sequences. Intermediate computation results are stored as control sequences `\.a/b[n]`.

Roughly speaking, the parser mechanism is as follows: at any given time the last found ``operator'' has its associated `until` macro awaiting some news from the token flow; first `getnext` expands

forward in the hope to construct some number, which may come from a parenthesized sub-expression, from some braced material, or from a digit by digit scan. After this number has been formed the next operator is looked for by the `getop` macro. Once `getop` has finished its job, `until` is presented with three tokens: the first one is the precedence level of the new found operator (which may be an end of expression marker), the second is the operator character token (earlier versions had here already some macro name, but in order to keep as much common code to `expr` and `floatexpr` common as possible, this was modified) of the new found operator, and the third one is the newly found number (which was encountered just before the new operator).

The `until` macro of the earlier operator examines the precedence level of the new found one, and either executes the earlier operator (in the case of a binary operation, with the found number and a previously stored one) or it delays execution, giving the hand to the `until` macro of the operator having been found of higher precedence.

A minus sign acting as prefix gets converted into a (unary) operator inheriting the precedence level of the previous operator.

Once the end of the expression is found (it has to be marked by a `\relax`) the final result is output as four tokens (five tokens since 1.09j) the first one a catcode 11 exclamation mark, the second one an error generating macro, the third one is a protection mechanism, the fourth one a printing macro and the fifth is `\.=a/b[n]`. The prefix `\xintthe` makes the output printable by killing the first three tokens.

### 11.3 Catcodes, ε-T<sub>E</sub>X and reload detection

The code for reload detection was initially copied from HEIKO OBERDIEK's packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

```

1 \begingroup\catcode61\catcode48\catcode32=10\relax%

### 11.7.4 Transforming all leaves within nested braced contents

1.4. Leaves must be of catcode 12... This is currently not a constraint (or rather not a new constraint) for *xintexpr* because formerly anyhow all data went through csname encapsulation and extraction via string.

In order to share code with the functioning of universal functions, which will be allowed to transform a number into an ople, the applied macro is supposed to apply one level of bracing to its output. Thus to apply this with an *xintfrac* macro such as `\xintiRound{0}` one needs first to define a wrapper which will expand it inside an added brace pair:

```

190 \def\foo#1{{\xintiRound{0}{#1}}}
191 {%
192     {{\expandafter\xintiexpr:\mapwithin#1#2%}
193      \expanded{\noexpand#1!\expandafter}\detokenize{#2}^}}%
194 }%
195 \def\xintiexpr:\mapwithin_checkempty #1!#2%
196 {%
197     \if ^#2\expandafter\xint_gob_til_^\else\expandafter\xintiexpr:\mapwithin_a\fi
198     #1!#2%
199 }%
200 \begingroup % should I check lccode s generally if corrupted context at load?
201 \catcode`[ 1 \catcode`] 2 \lccode`[`{ \lccode`}`]
202 \catcode`< 1 \catcode`> 2 \catcode`{ 12 \catcode`}` 12
203 \lowercase<\endgroup
204 \def\xintiexpr:\mapwithin_a #1{#2%
205 <%
206     \if{#2\xint_dothis<[\iffalse]\fi\xintiexpr:\mapwithin_a}\fi%

### 11.8.1 \xintexpr, \xintiexpr, \xintfloatexpr, \xintiiexpr

\xintiexpr and \xintfloatexpr have an optional argument since 1.1.

ATTENTION! 1.3d renamed \xinteval to \xintexpr etc...

Usage of \xintiRound{0} for \xintiexpr without optional [D] means that \xintiexpr ... \relax wrapper can be used to insert rounded-to-integers values in \xintiiexpr context: no post-fix [0] which would break it.

1.4a add support for the optional argument [D] for \xintiexpr being negative D, with same meaning as the 1.4a modified \xintRound from xintfrac.sty.

\xintiexpr mechanism was refactored at 1.4e so that rounding due to [D] optional argument uses raw format, not fixed point format on output, delegating fixed point conversion to an \XINTiexprprint now separated from \XINTexprprint.

In case of negative [D], \xintiexpr [D]... \relax internally has the [0] post-fix so it can not be inserted as sub-expression in \xintiiexpr without a num() or \xintiexpr ... \relax (extra) wrapper.

```

### 11.8.2 *\XINT\_expr\_wrap*, *\XINT\_iexpr\_wrap*, *\XINT\_flexpr\_wrap*

1.3e removes some leading space tokens which served nothing. There is no *\XINT\_iexpr\_wrap*, because *\XINT\_expr\_wrap* is used directly.

1.4e has *\XINT\_iexpr\_wrap* separated from *\XINT\_expr\_wrap*, thus simplifying internal matters as output printer for *\xintexpr* will not have to handle fixed point input but only extended-raw type input (i.e. A, A/B, A[N] or A/B[N]).

```

288 \def\XINT_expr_wrap {\XINTfstop\XINTexprprint.}%
289 \def\XINT_iexpr_wrap {\XINTfstop\XINTiexprprint.}%
290 \def\XINT_iexpr_wrap {\XINTfstop\XINTiiexprprint.}%
291 \def\XINT_flexpr_wrap {\XINTfstop\XINTflexprprint}%

```

### 11.8.3 *\XINTexprprint*, *\XINTiexprprint*, *\XINTiiexprprint*, *\XINTflexprprint*

Comments (still) currently under reconstruction.

1.4: this now requires \expanded context.  
 1.4e has a separate \XINTexprprint and \xintexprPrintOne.  
 1.4e has a breaking change of \XINTflexprprint and \xintfloatexprPrintOne which now requires \xintfloatexprPrintOne[D]{x} usage, with first argument in brackets.

```

#### 11.8.4 \xintthe, \xintthealign, \xinttheexpr, \xinttheiexpr, \xintthefloatexpr, \xinttheiiexpr

The reason why \xinttheiexpr et \xintthefloatexpr are handled differently is that they admit an optional argument which acts via a custom «printing» stage.

We exploit here that \expanded expands forward until finding an implicit or explicit brace, and that this expansion overrules \protected macros, forcing them to expand, similarly as \roman numeral expands \protected macros, and contrarily to what happens \*within\* the actual \expanded scope. I discovered this fact by testing (with pdftex) and I don't know where this is documented apart from the source code of the relevant engines. This is useful to us because there are contexts where we will want to apply a complete expansion before printing, but in purely numerical context this is not needed (if I converted correctly after dropping at 1.4 the \csname governed expansions; however I rely at various places on the fact that the xint macros are f-expandable, so I have tried to not use zillions of expanded all over the place), hence it is not needed to add the expansion overhead by default. But the \expanded here will allow \xintNewExpr to create macro with suitable modification or the printing step, via some hook rather than having to duplicate all macros here with some new «NE» meaning (aliasing does not work or causes big issues due to desire to support \xinteval also in «NE» context as sub-constituent. The \XINT:NHook:x:toblist is something else which serves to achieve this support of \*sub\* \xinteval, it serves nothing for the actual produced macros. For \xintdeffunc, things are simpler, but still we support the [N] optional argument of \xintiexpr and \xintfloatexpr, which required some work...).

The \expanded upfront ensures \xintthe mechanism does expand completely in two steps.

```

308 \def\xintthe      #1{\expanded\expandafter\xint_gobble_i\romannumeral`&&@#1}%

### 11.8.5 *\thexintexpr*, *\thexintiexpr*, *\thexintffloatexpr*, *\thexintiiexpr*

New with 1.2h. I have been for the last three years very strict regarding macros with *\xint* or *\XINT*, but well.

1.4. Definitely I don't like those. I will remove them at 1.5.

```

322 \let\thexintexpr     \xinttheexpr
323 \let\thexintiexpr    \xinttheiexpr
324 \let\thexintffloatexpr\xintthefloatexpr
325 \let\thexintiiexpr   \xinttheiiexpr

```

### 11.8.6 *\xintbareeval*, *\xintbareffloateval*, *\xintbareiieval*

At 1.4 added one expansion step via *\_start* macros. Triggering is expected to be via either *\romannumeral`^^@* or *\romannumeral0* is also ok

```

326 \def\xintbareeval    {\XINT_expr_start }%
327 \def\xintbareffloateval{\XINT_fexpr_start}%
328 \def\xintbareiieval  {\XINT_iiexpr_start}%

```

### 11.8.7 *\xintthebareeval*, *\xintthebareffloateval*, *\xintthebareiieval*

For matters of *\XINT\_NewFunc*

```

329 \def\XINT_expr_unlock    {\expandafter\xint_firstofone\romannumeral`&&@}%
330 \def\xintthebareeval     {\romannumeral0\expandafter\xint_stop_atfirstofone\romannumeral0\xintbareeval}%

359 }%
360 \let\thexintboolexpr\xinttheboolexpr

```

### 11.8.10 `\xintifboolexpr`, `\xintifboolfloatexpr`, `\xintifbooliexpr`

They do not accept comma separated expressions input.

```

361 \def\xintifboolexpr      #1{\romannumeral0\xintiiifnotzero {\xinttheexpr #1\relax}}%
362 \def\xintifboolfloatexpr #1{\romannumeral0\xintiiifnotzero {\xintthefloatexpr #1\relax}}%
363 \def\xintifbooliexpr     #1{\romannumeral0\xintiiifnotzero {\xinttheiexpr #1\relax}}%

```

### 11.8.11 `\xintifsgnexpr`, `\xintifsgnfloatexpr`, `\xintifsgniiexpr`

1.3d (2019/01/06).

They do not accept comma separated expressions.

```

364 \def\xintifsgnexpr      #1{\romannumeral0\xintiiifsgn {\xinttheexpr #1\relax}}%
365 \def\xintifsgnfloatexpr #1{\romannumeral0\xintiiifsgn {\xintthefloatexpr #1\relax}}%
366 \def\xintifsgniiexpr    #1{\romannumeral0\xintiiifsgn {\xinttheiexpr #1\relax}}%

```

### 11.8.12 Small bits we have to put somewhere

Some renaming and modifications here with release 1.2 to switch from using chains of `\romannumeral-`0` in order to gather numbers, possibly hexadecimals, to using a `\csname` governed expansion. In this way no more limit at 5000 digits, and besides this is a logical move because the `\xintexpr` parser is already based on `\csname...\\endcsname` storage of numbers as one token.

The limitation at 5000 digits didn't worry me too much because it was not very realistic to launch computations with thousands of digits... such computations are still slow with 1.2 but less so now. Chains or `\romannumeral` are still used for the gathering of function names and other stuff which I have half-forgotten because the parser does many things.

In the earlier versions we used the `lockscan` macro after a chain of `\romannumeral-`0` had ended gathering digits; this uses has been replaced by direct processing inside a `\csname...\\endcsname` and the macro is kept only for matters of dummy variables.

Currently, the parsing of hexadecimal numbers needs two nested `\csname...\\endcsname`, first to gather the letters (possibly with a hexadecimal fractional part), and in a second stage to apply

*TOC, xintkernel, xinttools, xintcore, xint, xintbinhex, xintgcd, xintfrac, xintseries, xintcfrac, xintexpr, xinttrig, xintlog*

\xintHexToDec to do the actual conversion. This should be faster than updating on the fly the number (which would be hard for the fraction part...).

372 }%
```

**\xintthecoords** 1.1 Wraps up an even number of comma separated items into pairs of TikZ coordinates; for use in the following way:

```
coordinates {\xintthecoords\xintfloatexpr ... \relax}
```

The crazyness with the \csname and unlock is due to TikZ somewhat STRANGE control of the TOTAL number of expansions which should not exceed the very low value of 100 !! As we implemented \XINT\_thecoords\_b in an "inline" style for efficiency, we need to hide its expansions.

Not to be used as \xintthecoords\xintthefloatexpr, only as \xintthecoords\xintfloatexpr (or \xintiexpr etc...). Perhaps \xintthecoords could make an extra check, but one should not accustom users to too loose requirements!

```
373 \def\xintthecoords#1%
374     {\romannumeral`&&@\expandafter\xINT_thecoords_a\romannumeral0#1}%

386     #1#2#3#4#5#6#7#8#9%
387     \xintthespaceSeparated_b}}
```

1.4c I add a space here to stop the \romannumeral`&&@ in case of empty input. But this space induces an extra un-needed space token after 9, 18, 27,... items before the last group of less than 9 items.

Fix (at 1.4h) is simple because I already use \expanded anyhow: I don't need at all the \romannumeral`&&@ which was first in \xintthespaceSeparated, let's move the first \expanded which was in \xintthespaceSeparated\_a to \xintthespaceSeparated, and remove the extra space here in \_c.

(Alternative would have been to put the space after #1 and accept a systematic trailing space, at least it is more aesthetic).

Again, I did have a test file, but it was not incorporated in my test suite, so I discovered the problem accidentally by compiling all files in an archive.

```
388 \def\xintthespaceSeparated_c !#1!#2^{#1}%
```

## 11.9 Hooks into the numeric parser for usage by the \xintdeffunc symbolic parser

This is new with 1.3 and considerably refactored at 1.4. See «Mysterious stuff».

```
389 \let\xINT:NEhook:f:one:from:one\expandafter
390 \let\xINT:NEhook:f:one:from:one:direct\empty
391 \let\xINT:NEhook:f:one:from:two\expandafter
392 \let\xINT:NEhook:f:one:from:two:direct\empty
393 \let\xINT:NEhook:x:one:from:two\empty
394 \let\xINT:NEhook:f:one:and:opt:direct      \empty
395 \let\xINT:NEhook:f:tacitzeroifone:direct  \empty
396 \let\xINT:NEhook:f:iitacitzeroifone:direct \empty
397 \let\xINT:NEhook:x:select:obey\empty
398 \let\xINT:NEhook:x:listsel\empty
399 \let\xINT:NEhook:f:reverse\empty
```

At 1.4 it was `\def\xINT:NEhook:f:from:delim:u #1#2^{#1#2^#2}` which was trick to allow automatic unpacking of a nutple argument to multi-arguments functions such as `gcd()` or `max()`. But this sacrificed the usage with a single numeric argument.

**1.4i (2021/06/11).**

More sophisticated code to check if the argument ople was actually a single number. Notice that this forces numeric types to actually use catcode 12 tokens, and `polexpr` diverges a bit using `P`, but actually always testing with `\if` not `\ifx`.

This is used by `gcd()`, `lcm()`, `max()`, `min()`, ``+`()`, ``*`()`, `all()`, `any()`, `xor()`.

The `nil` and `None` will give the same result due to the initial brace stripping done by `\XINT:NEhook:f:from:delim:` (there was even a prior brace stripping to provide the `#2` which is `empty` here for the `nil` and `{}` for the `None`).

```
400 \def\xINT:NEhook:f:from:delim:u #1#2^%
401 {%
402     \expandafter\xINT_fooof_checkifnumber\expandafter#1\string#2^%
403 }%
404 \def\xINT_fooof_checkifnumber#1#2^%
405 {%
406     \expandafter#1%
407     \romannumeral0\expanded{\if ^#2^{\else
408         \if\bgroup#2\noexpand\xINT_fooof_no\else
409             \noexpand\xINT_fooof_yes#2\fi\fi}%
410 }%
411 \def\xINT_fooof_yes#1^{\{#1}^}%
412 \def\xINT_fooof_no{\expandafter{\iffalse}\fi}%
```

**1.4i (2021/06/11).**

Same changes as for the other multiple arguments functions, making them again usable with a single numeric input.

Was at 1.4 `\def\xINT:NEhook:f:neval:from:braced:u#1#2^{#1{#2}}` which is not compatible with a single numeric input.

Used by `len()`, `first()`, `last()` but it is a potential implementation bug that the three share this as the location where expansion takes places is one level deeper for the support macro of `len()`.

The `None` is here handled as `nil`, i.e. it is unpacked, which is fine as the documentations says nutuples are unpacked.

This is somewhat complicated here due to the macro interfaces of `\xintFirstOne`, `\xintLastOne` and `\xintLength` which used a braced not a delimited argument, this forces here some re-grab which adds overhead.

To avoid this one would like to move the check to inside `{#2}`, but then there is a difficulty caused by the nil (or None), if we apply a string technique as it will hit the closing brace.

```

```

## 11.10 `\XINT_expr_getnext`: fetch some value then an operator and present them to last waiter with the found operator precedence, then the operator, then the value

Big change in 1.1, no attempt to detect braced stuff anymore as the [N] notation is implemented otherwise. Now, braces should not be used at all; one level removed, then \roman{`0} expansion.

Refactored at 1.4 to put expansion of `\XINT_expr_getop` after the fetched number, thus avoiding it to have to fetch it (which could happen then multiple times, it was not really important when it was only one token in pre-1.4 `xintexpr`).

Allow `\xintexpr\relax` at 1.4.

Refactored at 1.4 the articulation `\XINT_expr_getnext/XINT_expr_func/XINT_expr_getop`. For some legacy reason the first token picked by `getnext` was soon turned to catcode 12. The next ones after the first were not a priori stringified but the first token was, and this made allowing things such as `\xintexpr\relax`, `\xintexpr,,\relax`, `[]`, `1+()`, `[:] etc...` complicated and requiring each time specific measures.

The `\expandafter` chain in `\XINT_expr_put_op_first` is an overhead related to an 1.4 attempt, the "varvalue" mechanism. I.e.: expansion of `\XINT_expr_var_foo` is `{\XINT_expr_varvalue_foo }` and then for example `\XINT_expr_varvalue_foo` expands to `{4/1[0]}`. The mechanism was originally conceived to have only one token with idea its makes things faster. But the `xintfrac` macros break

with syntax such as `\xintMul\foo\bar` and `\foo` expansion giving braces. So at 1.4c I added here these `\expandafter`, but this is REALLY not satisfactory because the `\expandafter` are needed it seems only for this variable "varvalue" mechanism.

See also the discussion of `\XINT_expr_op_` which distinguishes variables from functions.

After a 1.4g refactoring it would be possible to drop here the `\expandafter` if the `\XINT_expr_var_foo` macro was defined to f-expand to {actual expanded value (as ople)} for example explicit `\{\{3\}\}`. I have to balance the relative weights of doing always the `\expandafter` but they are needed only for the case the value was encapsulated in a variable, and of never doing the `\expandafter` and ensure f-expansion of the `_var_foo` gives explicit value (now that the refactoring let it be f-expanded, and the case of fake variables omit and abort in particular was safely separated instead of being treated like other and imposing restrictions on general variable handling), and then there is the overhead of possibly moving around many digits in the #1 of `\XINT_expr_put_op_first`.

```
442 \def\xintexpr_getnext #1%
443 {%
444     \expandafter\xintexpr_put_op_first\romannumeral`&&@%
445     \expandafter\xintexpr_getnext_a\romannumeral`&&#1%
446 }%
447 \def\xintexpr_put_op_first #1#2#3{\expandafter#2\expandafter#3\expandafter{#1}}%

477     0\expandafter\xintexpr_fetch_as_number\fi
```

```

478   \expandafter\XINT_expr_getnext_a\number #1%
479 }%
480 \def\XINT_expr_fetch_as_number
481   \expandafter\XINT_expr_getnext_a\number #1%
482 {%
483   \expanded{{{\number#1}}}\expandafter}\romannumeral`&&@\XINT_expr_getop
484 }%

```

This is the key initial dispatch component. It has been refactored at 1.4g to give priority to identifying letter and digit tokens first. It thus combines former `\XINT_expr_getnextfork`, `\XINT_expr_scan_nbr_or_func` and `\XINT_expr_scanfunc`. A branch of the latter having become `\XINT_expr_startfunc`. The handling of non-catcode 11 underscore `_` has changed: it is now skipped completely like the `+`. Formerly it would cause an infinite loop because it triggered first insertion of a nil variable, (being confused with a possible operator at a location where one looks for a value), then tacit multiplication (being now interpreted as starting some name), and then it came back to `getnextfork` creating loop. The `@` of catcode 12 could have caused the same issue if it was not handled especially because it is used in the syntax as special variable for recursion hence was recognized even if of catcode 12. Anyway I could have handled the `_` like the `@`, to avoid this problem of infinite loop with a non-letter underscore used as first character but decided finally to have it be ignored (it is already ignored if among digits, but it can be a constituent of a function of variable name). It is not ignored of course if of catcode 11. It may then start a variable or function name, but only for use by the package (by `polexpr` for example), not by users.

Then the matter is handed over to specialized routines: gathering digits of a number (inclusive of a decimal mark, an exponential part) or letters of a function or variable. And we have to intercept some tokens to implement various functionalities.

In each dothis/orthat structure, the first encountered branches are usually handled slower than the next, because `\if..fi` test cost less than grabbing tokens. The exception is in the first one where letters pass through slightly faster than digits, presumably because the `\ifnum` test is more costly. Prior to this 1.4g refactoring the case of a starting letter of a variable or function name was handled last, it is now handled first. Now, this is only first letter...

Here are the various possibilities in order that they appear below (the indicative order of speed of treatment is given as a number).

- 1 tokens of catcode letter start a variable or function name
- 2 digits (I apply `\string` for the test, but I will have to review, it seems natural anyhow to require digits to be of catcode 12 and this is in fact basically done by the package, `\numexpr` does not work if not the case.),
- 7 support for Python-like \* "unpacking" unary operator (added at 1.4),
- 6 support for [ as opener for the [...] tuple constructor (1.4),
- 5 support for the minus as unary operator of variable precedence,
- 4 support for @ as first character of special variables even if not letter,
- 3 support for opening parentheses (possibly triggering tacit multiplication),
- 13 support for skipping over ignored + character,
- 12 support for numbers starting with a decimal point,
- 11 support for the `+`() and `\*`() functions,
- 10 support for the !() function,
- 9 support for the ?() function,
- 8 support for " for input of hexadecimal numbers. But `xintbinhex` must be loaded explicitly by user.
- 17 support for `\xintdeffunc` via special handling of # token,
- 16 support for ignoring \_ if not of catcode 11 and at start of numbers or names (this 1.4g change fixes `\xinteval{_4}` creating infinite loop)
- 15 support for inserting "nil" in front of operators, as needed in particular for the Python slicing syntax. This covers the comma, the :, the ] and the ) and also the ; although I don't think

using ; to delimit nil is licit.

-14 support for inserting 0 as missing value if / or ^ are encountered directly. This 1.4g changes avoids \xinteval{/3} causing unrecoverable low level errors from \xintDiv receiving only one argument.

I did not see here other bad syntax to protect.

The handling of "nil" insertion penalizes Python slicing but anyway time differences in the 14-15-16-17 group are less than 5%. The alternative will be to do some positive test for the targets (:, ], the comma and closing parenthesis) and do this in the prior group but this then penalizes others. Anyway. This is all negligible compared to actual computations...

Note: the above may not be in sync with code as it is extremely time-consuming to maintain correspondence in case of re-factoring.

The ` syntax is here used for special constructs like `+(..), `\*(..) where + or \* will be treated as functions. Current implementation picks only one token (could have been braced stuff), here it will be + or \*, and via \XINT\_expr\_op\_` this then becomes a suitable \XINT\_{expr|iiexpr|flexpr}\_func\_+ (or \*). Documentation says to use `+(..), but `+(...) is also valid. The opening parenthesis must be there, it is not allowed to require some expansion.

```

### 11.11 \XINT\_expr\_startint

11.11.1	Integral part (skipping zeroes) . . . . .	334
11.11.2	Fractional part . . . . .	336
11.11.3	Scientific notation . . . . .	337
11.11.4	Hexadecimal numbers . . . . .	338
11.11.5	\XINT_expr_startfunc: collecting names of functions and variables . . . . .	341
11.11.6	\XINT_expr_func: dispatch to variable replacement or to function execution . . . . .	341

1.2 release has replaced chains of \romannumeral-`0 by \csname governed expansion. Thus there is no more the limit at about 5000 digits for parsed numbers.

In order to avoid having to lock and unlock in succession to handle the scientific part and adjust the exponent according to the number of digits of the decimal part, the parsing of this decimal part counts on the fly the number of digits it encounters.

There is some slight annoyance with `\xintiiexpr` which should never be given a [n] inside its `\csname .=<digits>\endcsname` storage of numbers (because its arithmetic uses the ii macros which know nothing about the [N] notation). Hence if the parser has only seen digits when hitting something else than the dot or e (or E), it will not insert a [0]. Thus we very slightly compromise the efficiency of `\xintexpr` and `\xintfloatexpr` in order to be able to share the same code with `\xintiiexpr`.

Indeed, the parser at this location is completely common to all, it does not know if it is working inside `\xintexpr` or `\xintiiexpr`. On the other hand if a dot or a e (or E) is met, then the (common) parser has no scruples ending this number with a [n], this will provoke an error later if that was within an `\xintiiexpr`, as soon as an arithmetic macro is used.

As the gathered numbers have no spaces, no pluses, no minuses, the only remaining issue is with leading zeroes, which are discarded on the fly. The hexadecimal numbers leading zeroes are stripped in a second stage by the `\xintHexToDec` macro.

With 1.2, `\xinttheexpr .\relax` does not work anymore (it did in earlier releases). There must be digits either before or after the decimal mark. Thus both `\xinttheexpr 1.\relax` and `\xinttheexpr .\relax` are legal.

Attention at this location #1 was of catcode 12 in all versions prior to 1.4.

We assume anyhow that catcodes of digits are 12... .

```

```

### 11.11.1 Integral part (skipping zeroes)

1.2 has modified the code to give highest priority to digits, the accelerating impact is non-negligible. I don't think the doubled \string is a serious penalty.

(reference to \string is obsolete: it is only used in the test but the tokens are not submitted to \string anymore)

```

562 {%
563     \iffalse{{{\fi}}}\expandafter}\romannumeral`&&@\xint_expr_getop_a#2%
564 }%

```

With 1.2d the tacit multiplication in front of a variable name or function name is now done with a higher precedence, intermediate between the common one of \* and / and the one of ^. Thus x/2y is like x/(2y), but x^2y is like x^2\*y and 2y! is not (2y)! but 2\*y!.

Finally, 1.2d has moved away from the \_scan macros all the business of the tacit multiplication in one unique place via \xint\_expr\_getop. For this, the ending token is not first given to \string as was done earlier before handing over back control to \xint\_expr\_getop. Earlier we had to identify the catcode 11 ! signaling a sub-expression here. With no \string applied we can do it in \xint\_expr\_getop. As a corollary of this displacement, parsing of big numbers should be a tiny bit faster now.

Extended for 1.21 to ignore underscore character \_ if encountered within digits; so it can serve as separator for better readability.

It is not obvious at 1.4 to support [] for three things: packing, slicing, ... and raw xintfrac syntax A/B[N]. The only good way would be to actually really separate completely \xintexpr, \xintfloatexpr and \xintiexpr code which would allow to handle both / and [] from A/B[N] as we handle e and E. But triplicating the code is something I need to think about. It is not possible as in pre 1.4 to consider [ only as an operator of same precedence as multiplication and division which was

the way we did this, but we can use the technique of fake operators. Thus we intercept hitting a [ here, which is not too much of a problem as anyhow we dropped temporarily  $3*[1,2,3]+5$  syntax so we don't have to worry that  $3[1,2,3]$  should do tacit multiplication. I think only way in future will be to really separate the code of the three parsers (or drop entirely support for  $A/B[N]$ ; as 1.4 has modified output of \xinteval to not use this notation this is not too dramatic).

Anyway we find a way to inject here the former handling of [N], which will use a delimited macro to directly fetch until the closing]. We do still need some fake operator because  $A/B[N]$  is  $(A/B)$  times  $10^N$  and the /B is allowed to be missing. We hack this using the which is not used currently as operator elsewhere in the syntax and need to hook into \XINT\_expr\_getop\_b. No finally I use the null char. It must be of catcode 12.

1.4f had \_getop here, but let's jump directly to \_getop\_a.

### 11.11.2 Fractional part

Annoying duplication of code to allow 0. as input.

1.2a corrects a very bad bug in 1.2 \XINT\_expr\_gobz\_scandec\_b which should have stripped leading zeroes in the fractional part but didn't; as a result \xinttheexpr 0.01\relax returned 0 =:-((( Thanks to Kroum Tzanev who reported the issue. Does it improve things if I say the bug was introduced in 1.2, it wasn't present before ?

1.4f had *\_getop* here, but let's jump directly to *\_getop\_a*.

#### 11.11.4 Hexadecimal numbers

1.2d has moved most of the handling of tacit multiplication to *\XINT\_expr\_getop*, but we have to do some of it here, because we apply *\string* before calling *\XINT\_expr\_scanhexI\_aa*. I do not insert the *\** in *\XINT\_expr\_scanhexI\_a*, because it is its higher precedence variant which will be expected, to do the same as when a non-hexadecimal number prefixes a sub-expression. Tacit multiplication in front of variable or function names will not work (because of this *\string*).

Extended for 1.2l to ignore underscore character *\_* if encountered within digits.

(some above remarks have been obsoleted for some long time, no more applied *\string* since 1.4)

Notice that internal representation adds a [N] part only in case input used "DDD.dddd form, for compatibility with *\xintiiexpr* which is not compatible with such internal representation.

At 1.4g a very long-standing bug was fixed: input such as "\foo broke the parser because (incredibly) the \foo token was picked up unexpanded and ended up as is in an \ifcat !

Another long-standing bug was fixed at 1.4g: contrarily to the decimal case, here in the hexadecimal input leading zeros were not trimmed. This was ok, because formerly *\xintHexToDec* trimmed leading zeros, but at 1.2m 2017/07/31 *xintbinhex.sty* was modified and this ceased being the case. But I forgot to upgrade the parser here at that time. Leading zeros would in many circumstances (presence of a fractional part, or *\xintiiexpr* context) lead to wrong results. Leading zeros are now trimmed during input.

### 11.11.5 \XINT\_expr\_startfunc: collecting names of functions and variables

At 1.4 the first token left over has not been submitted to \string. We also know it is not a control sequence. So we can test catcode to identify if operator is found. And it is allowed to hit some operator such as a closing parenthesis we will then insert the «nil» value (edited: which however will cause certain breakage of the infix binary operators: I notice I did not insert None {{}} but nil {}, perhaps by oversight).

There was prior to 1.4 solely the dispatch in \XINT\_expr\_scanfunc\_b but now we do it immediately and issue \XINT\_expr\_func only in certain cases.

Comments here have been removed because 1.4g did a refactoring and renamed \XINT\_expr\_scanfunc to \XINT\_expr\_startfunc, moving half of it earlier inside the getnextfork macros.

```
820 \def\XINT_expr_startfunc #1{\expandafter\XINT_expr_func\expanded\bgroup#1\XINT_expr_scanfunc_a}%
821 \def\XINT_expr_scanfunc_a #1%
822 {%
823     \expandafter\XINT_expr_scanfunc_b\romannumeral`&&@#1%
824 }%
```

This handles: 1) (indirectly) tacit multiplication by a variable in front a of sub-expression, 2) (indirectly) tacit multiplication in front of a \count etc..., 3) functions which are recognized via an encountered opening parenthesis (but later this must be disambiguated from variables with tacit multiplication) 4) 5) 6) 7) acceptable components of a variable or function names: @, underscore, digits, letters (or chars of category code letter.)

The short lived 1.2d which followed the even shorter lived 1.2c managed to introduce a bug here as it removed the check for catcode 11 !, which must be recognized if ! is not to be taken as part of a variable name. Don't know what I was thinking, it was the time when I was moving the handling of tacit multiplication entirely to the \XINT\_expr\_getop side. Fixed in 1.2e.

I almost decided to remove the \ifcat\relax test whose rôle is to avoid the \string#1 to do something bad is the escape char is a digit! Perhaps I will remove it at some point ! I truly almost did it, but also the case of no escape char is a problem (\string\0, if \0 is a count ...)

The (indirectly) above means that via \XINT\_expr\_func then \XINT\_expr\_op\_\_ one goes back to \XINT\_expr\_getop then \XINT\_expr\_getop\_b which is the location where tacit multiplication is now centralized. This makes the treatment of tacit multiplication for situations such as <variable>\count or <variable>\xintexpr..\relax, perhaps a bit sub-optimal, but first the variable name must be gathered, second the variable must expand to its value.

```

### 11.11.6 \XINT\_expr\_func: dispatch to variable replacement or to function execution

Comments written 2015/11/12: earlier there was an \ifcsname test for checking if we had a variable in front of a (, for tacit multiplication for example in x(y+z(x+w)) to work. But after I had implemented functions (that was yesterday...), I had the problem if was impossible to re-declare a

variable name such as "f" as a function name. The problem is that here we can not test if the function is available because we don't know if we are in expr, iiexpr or floatexpr. The `\xint_c_ii^v` causes all fetching operations to stop and control is handed over to the routines which will be expr, iiexpr ou floatexpr specific, i.e. the `\XINT_{expr|iiexpr|flexpr}_op_{`|_}` which are invoked by the `until_<op>_b` macros earlier in the stream. Functions may exist for one but not the two other parsers. Variables are declared via one parser and usable in the others, but naturally `\xintiiexpr` has its restrictions.

Thinking about this again I decided to treat a priori cases such as `x(...)` as functions, after having assigned to each variable a low-weight macro which will convert this into `_getop\.=<value of x>*(...)`. To activate that macro at the right time I could for this exploit the "onliteral" intercept, which is parser independent (1.2c).

This led to me necessarily to rewrite partially the seq, add, mul, subs, iter ... routines as now the variables fetch only one token. I think the thing is more efficient.

1.2c had `\def\xINT_expr_func #1(#2{\xint_c_ii^v #2[#1]}`

In `\XINT_expr_func` the #2 is \_ if #1 must be a variable name, or #2=` if #1 must be either a function name or possibly a variable name which will then have to be followed by tacit multiplication before the opening parenthesis.

The `\xint_c_ii^v` is there because `_op_`` must know in which parser it works. Dispensious for \_. Hence I modify for 1.2d.

```
837 \def\xINT_expr_func #1(#2{\if _#2\xint_dothis{\XINT_expr_op_{[#1]}}\fi
838                               \xint_orthat{[#1]\xint_c_ii^v #2}%)%
```

## 11.12 `\XINT_expr_op_``: launch function or pseudo-function, or evaluate variable and insert operator of multiplication in front of parenthesized contents

The "onliteral" intercepts is for bool, tog, protect, ... but also for add, mul, seq, etc... Genuine functions have expr, iiexpr and flexpr versions (or only one or two of the three) and trigger here the use of the suitable parser-dependant form. The former (pseudo functions and functions handling dummy variables) first trigger a parser independent mechanism.

With 1.2c "onliteral" is also used to disambiguate a variable followed by an opening parenthesis from a function and then apply tacit multiplication. However as I use only a `\ifcsname` test, in order to be able to re-define a variable as function, I move the check for being a function first. Each variable name now has its `onliteral_<name>` associated macro. This used to be decided much earlier at the time of `\XINT_expr_func`.

The advantage of 1.2c code is that the same name can be used for a variable or a function.

### 1.4i (2021/06/11) [commented 2021/06/11].

The 1.2c abuse of «onliteral» for both tacit multiplication in front of an opening parenthesis and «generic» functions or pseudo-functions meant that the latter were vulnerable against user redefinition of a function name as a variable name. This applied to subs, subsm, subsn, seq, add, mul, ndseq, ndmap, ndfillraw, bool, tog, protect, qint, qfrac, qfloat, qraw, random, qrand, rbit and the most susceptible in real life was probably "seq".

Now variables have an associated «var\*» named macro, not «onliteral».

In passing I refactor here in a `\romannumeral` inspired way how `\csname` and TeX booleans are intertwined, minimizing `\expandafter` usage.

### 11.13 \XINT\_expr\_op\_\_: replace a variable by its value and then fetch next operator

The 1.1 mechanism for \XINT\_expr\_var\_<varname> has been modified in 1.2c. The <varname> associated macro is now only expanded once, not twice. We arrive here via \XINT\_expr\_func.

At 1.4 \XINT\_expr\_getop is launched with accumulated result on its left. But the omit and abort keywords are implemented via fake variables which rely on possibility to modify incoming upfront tokens. If we did here something such as

\_var\_#1\expandafter\endcsname\romannumeral`^^@\XINT\_expr\_getop

the premature expansion of getop would break the var OMIT and var\_ABORT mechanism. Thus we revert to former code which locates an \XINT\_expr\_getop (call it \_legacy) before the tokens from the variable expansion (in xintexpr < 1.4 the normal variables expanded to a single token so the overhead was not serious) so we can expand fake variables first.

Abusing variables to manipulate the incoming token stream is a bit bad, usually I prefer functions for this (such as the break() function) but then I have to define 3 macros for the 3 parsers.

This trick of fake variables puts thus a general overhead at various locations, and the situation here is REALLY not satisfactory. But 1.4 has (had) to be released now.

Even if I could put the \csname XINT\_expr\_var\_foo\endcsname upfront, which would then be f-expanded, this would still need \XINT\_expr\_put\_op\_first to use its \expandafter's as long as \XINT\_expr\_var\_foo expands to {\XINT\_expr\_varvalue\_foo} with a not-yet expanded \XINT\_expr\_var\_value.

I could let \XINT\_expr\_var\_foo expand to \expandafter{\XINT\_expr\_varvalue\_foo} allowing then (if it gets f-expanded) probably to drop the \expandafter in \XINT\_expr\_put\_op\_first. But I can not consider this option in the form

\_var\_foo\expandafter\endcsname\romannumeral`^^@\XINT\_expr\_getop

until the issue with fake variables such as omit and abort which must act before \XINT\_expr\_getop has some workaround. This could be implemented here with some extra branch, i.e. there would not be some \XINT\_expr\_var OMIT but something else filtered out in the \else branch here.

The above comments mention only omit and abort, but the case of real dummy variables also needs

consideration.

At 1.4g, I test first for existence of `\XINT_expr_onliteral_foo`.

Updated for 1.4i: now rather existence of `\XINT_expr_var*_foo` is tested.

This is a trick which allows to distinguish actual or dummy variables from really fake variables omit and abort (must check if there are others). For the real or dummy variables we can trigger the expansion of the `\XINT_expr_getop` before the one of the variable. I could test vor varvalue\_foo but this applies only to real variables not dummy variables. Actual and dummy variables are thus handled slightly faster at 1.4g as there is less induced moving around (the `\expandafter` chain in `\XINT_expr_put_op_first` still applies at this stage, as I have not yet re-examined the var/varvalue mechanism). And the test for var\_foo is moved directly inside the `\csname` construct in the `\else` branch which now handles together fake variables and non-existing variables.

I only have to make sure dummy variables are really safe being handled this way with the getop action having been done before they expand, but it looks ok. Attention it is crucial that if `\XINT_expr_getop` finds a `\relax` it inserts `\xint_c_\relax` so the `\relax` token is still there!

With this refactoring the `\XINT_expr_getop_legacy` is applied only in case of non-existent variables or fake variables omit/abort or things such as nil, None, false, true, False, True.

If user in interactive mode fixes the variable name, the `\XINT_expr_var_foo` expanded once with deliver `\{ \XINT_expr_varvalue_foo }` (if not dummy), and the braces are maintained by `\XINT_expr_getop_legacy`.

```

## 11.14 `\XINT_expr_getop`: fetch the next operator or closing parenthesis or end of expression

Release 1.1 implements multi-character operators.

1.2d adds tacit multiplication also in front of variable or functions names starting with a letter, not only a @ or a \_ as was already the case. This is for (x+y)z situations. It also applies higher precedence in cases like x/2y or x/2@, or x/2max(3,5), or x/2\xintexpr 3\relax.

In fact, finally I decide that all sorts of tacit multiplication will always use the higher precedence.

Indeed I hesitated somewhat: with the current code one does not know if `\XINT_expr_getop` is invoked after a closing parenthesis or because a number parsing ended, and I felt distinguishing

the two was unneeded extra stuff. This means cases like  $(a+b)/(c+d)(e+f)$  will first multiply the last two parenthesized terms.

1.2q adds tacit multiplication in cases such as  $(1+1)3$  or  $5!7!$

1.4 has simplified coding here as `\XINT_expr_getop` expansion happens at a time when a fetched value has already being stored.

Prior to 1.4g there was an `\if _#1\xint_dothis\xint_secondofthree\fi` because the `_` can be used to start names, for private use by package (for example by `polexpr`). But this test was silly because these usages are only with a `_` of catcode 11. And allowing non-catcode 11 `_` also to trigger tacit multiplication caused an infinite loop in collaboration with `\XINT_expr_scanfunc`, see explanations there (now removed after refactoring, see `\XINT_expr_startfunc`).

The situation with the `@` is different because we must allow it even as catcode 12 as a name, as it used in the syntax and must work the same if of catcode 11 or 12. No infinite loop because it is filtered out by one of the `\XINT_expr_getnextfork` macros.

The check for `:` to send it to `thirdofthree` "getop" branch is needed, last time I checked, because during some part of at least `\xintdeffunc`, some scantokens are done which need to work with the `:` of catcode 11, and it would be misconstrued to start a name if not filtered out.

```

890 \def\XINT_expr_getop #1%
891 {%
892     \expandafter\XINT_expr_getop_a\romannumeral`&&#1%
893 }%
894 \catcode`* 11
895 \def\XINT_expr_getop_a #1%
896 {%
897     \ifx \relax #1\xint_dothis\xint_firstofthree\fi
898     \ifcat \relax #1\xint_dothis\xint_secondofthree\fi
899     \ifnum\xint_c_ix<1\string#1 \xint_dothis\xint_secondofthree\fi
900     \if :#1\xint_dothis \xint_thirdofthree\fi
901     \if @#1\xint_dothis \xint_secondofthree\fi
902     \if (#1\xint_dothis \xint_secondofthree\fi %)
903     \ifcat a#1\xint_dothis \xint_secondofthree\fi
904     \xint_orthat \xint_thirdofthree

```

Formerly `\XINT_expr_foundend` as `firstofthree` but at 1.4g let's simply insert `\xint_c_` as the `#1` is `\relax` (and anyhow a place-holder according to remark in definition of `\XINT_expr_foundend`

```
905     \xint_c_
```

Tacit multiplication with higher precedence. Formerly `\XINT_expr_precedence_***` was used, renamed to `\XINT_expr_prec_tacit` at 1.4g in case a backport is done of the `\bnumdefinfix` from `bnumexpr`.

```
906     {\XINT_expr_prec_tacit *}%
```

This is only location which jumps to `\XINT_expr_getop_b`. At 1.4f and perhaps for old legacy reasons this was `\expandafter\XINT_expr_getop_b\string#1` but I see no reason now for applying `\string` to `#1`. Removed at 1.4g. And the `#1` now moved out of the `secondofthree` and `thirdofthree` branches.

```

907     \XINT_expr_getop_b
908     #1%
909 }%
910 \catcode`* 12

```

`\relax` is a place holder here. At 1.4g, we don't use `\XINT_expr_foundend` anymore in `\XINT_expr_getop_a` which was slightly refactored, but it is used elsewhere.

Attention that keeping a \relax around if \XINT\_expr\_getop hits it is crucial to good functioning of dummy variables after 1.4g refactoring of \XINT\_expr\_op\_\_, the \relax being used as delimiter by dummy variables, and \XINT\_expr\_getop is now expanded before the variable itself does its thing.

```
911 \def\XINT_expr_foundend {\xint_c_ \relax}%
```

? is a very special operator with top precedence which will check if the next token is another ?, while avoiding removing a brace pair from token stream due to its syntax. Pre 1.1 releases used : rather than ??, but we need : for Python like slices of lists.

null char is used as hack to implement A/B[N] raw input at 1.4. See also \XINT\_expr\_scanint\_c.

Memo: 1.4g, the token fetched by \XINT\_expr\_getop\_b has not anymore been previously submitted in \XINT\_expr\_getop\_a to \string.

Multi-character operators have an associated itself macro at each stage of decomposition starting at two characters. Here, nothing imposes to the operator characters not to be of catcode letter, this constraint applies only on the first character and is done via \XINT\_expr\_getop\_a, to handle in particular tacit multiplication in front of variable or function names.

But it would be dangerous to allow letters in operator characters, again due to existence of variables and functions, and anyhow there is no user interface to add such custom operators. However in bnumexpr, such a constraint does not exist.

I don't worry too much about efficiency here... and at 1.4g I have re-written for code readability only. Once we see that #1#2 is not a candidate to be or start an operator, we need to check if single-character operator #1 is really an operator and this is done via the existence of the precedence token.

Unfortunately the 1.4g refactoring of the scanop macros had a bad bug: \XINT\_expr\_scanop\_c inserted \romannumeral`^@ in stream but did not grab a token first so a space would stop the \romannumeral and then the #2 in \XINT\_expr\_scanop\_d was not pre-expanded and ended up alone in \ifcat. It is too distant in the past the time when I wrote the core of xintexpr in 2013... older and dumber now.

## 11.15 Expansion spanning; opening and closing parentheses

These comments apply to all definitions coming next relative to execution of operations from parsing of syntax.

Refactored (and unified) at 1.4. In particular the 1.4 scheme uses `op`, `exec`, `check-`, and `checkp`. Formerly it was `until_a` (`check-`) and `until_b` (now split into `checkp` and `exec`).

This way neither `check-` nor `checkp` have to grab the accumulated number so far (top of stack if you like) and besides one never has to go back to `check-` from `checkp` (and neither from `check-`).

Prior to 1.4, accumulated intermediate results were stored as one token, but now we have to use `\expanded` to propagate expansion beyond possibly arbitrary long braced nested data. With the 1.4 refactoring we do this only once and only grab a second time the data if we actually have to act upon it.

Version 1.1 had a hack inside the `until` macros for handling the `omit` and `abort` in iterations over dummy variables. This has been removed by 1.2c, see the subsection where `omit` and `abort` are discussed.

Exceptionally, the `check-` is here abbreviated to `check`.

## 11.17 The minus as prefix operator of variable precedence level

Inherits the precedence level of the previous infix operator, if the latter has at least the precedence level of binary + and -, i.e. currently 12.

Refactored at 1.4.

At 1.4g I belatedly observe that I have been defining architecture for op\_-xvi but such operator can never be created, because there are no infix operators of precedence level 16. Perhaps in the past this was really needed? But now such 16 is precedence level of tacit multiplication which is implemented simply by the \XINT\_expr\_prec\_tacit token, there is no macro check\_-\*\*\* which would need an op\_-xvi.

For the record: at least one scenario exists which creates tacit multiplication in front of a unary -, it is 2\count0 which first generates tacit multiplication then applies \number to \count0, but the operator is still \*, so this triggers only \XINT\_expr\_op\_-xiv, not -xvi.

At 1.4g we need 17 and not 18 anymore as the precedence of unary minus following power operators ^ and \*\*. The needed \xint\_c\_xvii creation was added to xintkernel.sty.

## 11.19 Infix operators

11.19.1	&&,   , //, /:, +, -, *, /, ^, **, 'and', 'or', 'xor', and 'mod'	352
11.19.2	.., ..[ , and ].. for a..b and a..[b]..c syntax	354
11.19.3	<, >, ==, <=, >=, != with Python-like chaining	356
11.19.4	Support macros for .., ..[ and ]..	358

1.2d adds the `***` for tying via tacit multiplication, for example `x/2y`. Actually I don't need the `_itself` mechanism for `***`, only a precedence.

At 1.4b we must make sure that the `!` in expansion of `\XINT_expr_itself_!=` is of catcode 12 and not of catcode 11. This is because implementation of chaining of comparison operators proceeds via inserting the `itself` macro directly into upcoming token stream, whereas formerly such `itself` macros would be expanded only in a `\csname... \endcsname` context.

```
1143 \catcode`& 12 \catcode`! 12
1144 \xintFor* #1 in {{==}{!=}{<=}{>}{&&}{||}{//}{/:}{..}{[]}{.}{}}{%
1145   \do {\expandafter\def\csname XINT_expr_itself_#1\endcsname {#1}}%
1146 \catcode`& 7 \catcode`! 11
```

### 11.19.1 `&&`, `||`, `//`, `/:`, `+`, `-`, `*`, `/`, `^`, `**`, `'and'`, `'or'`, `'xor'`, and `'mod'`

Single character boolean operators `&` and `|` had been deprecated since 1.1 and finally got removed (together with `=` comparison test) from syntax at 1.4g.

Also, at 1.4g I finally decide to enact the switch to right associativity for the power operators `^` and `**`.

This goes via inserting into the `checkp` macros not anymore the precedence `chardef` token (which now only serves as left precedence, inserted in the token stream) but in its place an `\xint_c_<roman>` token holding the right precedence. Which is also transmitted to spanned unary minus operators.

Here only levels 12, 14, and 17 are created as right precedences.

#6 and #7 got permuted and the new #7 is directly a control sequence. Also #3 and #4 are now integers which need `\romannumeral`. The change in `\XINT_expr_defbin_c` does not propagate as it is re-defined shortly thereafter.

### 11.19.2 ...[ and ].. for a..b and a..[b]..c syntax

The 1.4 `exec_..[` macros (which do no further expansion!) had silly `\expandafter` doing nothing for the sole reason of sharing a common `\XINT_expr_defbin_c` as used previously for the `+`, `-` etc... operators. At 1.4b we take the time to set things straight and do other similar simplifications.

```

Single character comparison operator = had been deprecated for many years (but I can't find since when precisely; & and | were deprecated at 1.1 as since in CHANGES.md) and it finally got removed from syntax at 1.4g, as well as & and |.

Attention that third token here is left in stream by defbin\_b, then also by defbin\_c and is picked up as #2 of defbin\_d. Had to work around TeX accepting only 9 arguments. Why did it not start counting at #0 like all decent mathematicians do?

#### 11.19.4 Support macros for ..[ and ].

**\xintSeq:tl:x** Commence par remplacer a par ceil(a) et b par floor(b) et renvoie ensuite les entiers entre les deux, possiblement en décroissant, et extrémités comprises. Si a=b est non entier en obtient donc ceil(a) et floor(a). Ne renvoie jamais une liste vide.

Note: le a..b dans \xintfloatexpr utilise cette routine.

```

**\xintSeqB:tl:x** At 1.4, delayed expansion of start and step done here and not before, for matters of *\xintdeffunc* and «NEhooks».

The float variant at 1.4 is made identical to the exact variant. I.e. stepping is exact and comparison to the range limit too. But recall that *a/b* input will be converted to a float. To handle *1/3* step for example still better to use *\xintexpr 1..1/3..10\relax* for example inside the *\xintfloateval*.

## 11.20 Square brackets [] both as a container and a Python slicer

Refactored at 1.4

The architecture allows to implement separately a «left» and a «right» precedence and this is crucial.

11.20.1 [...] as «oneple» constructor . . . . .	360
11.20.2 [...] brackets and : operator for NumPy-like slicing and item indexing syntax . . . . .	361
11.20.3 Macro layer implementing indexing and slicing . . . . .	363

### 11.20.1 [...] as «oneple» constructor

In the definition of `\XINT_expr_op_obrace` the parameter is trash `{}`. The `[` is intercepted by the `getnextfork` and handled via the `\xint_c_ii^v` highest precedence trick to get `op_obrace` executed.

### 11.20.2 [...] brackets and : operator for NumPy-like slicing and item indexing syntax

The opening bracket [ for the ntuple constructor is filtered out by \XINT\_expr\_getnextfork and becomes «obracket» which behaves with precedence level 2. For the [...] Python slicer on the other hand, a real operator [ is defined with precedence level 4 (it must be higher than precedence level of commas) on its right and maximal precedence on its left.

Important: although slicing and indexing shares many rules with Python/NumPy there are some significant differences: in particular there can not be any out-of-range error generated, slicing applies also to «oples» and not only to «ntuple», and nested lists do not have to have their leaves at a constant depth. See the user manual.

Currently, NumPy-like nested (basic) slicing is implemented, i.e [a:b, c:d, N, e:f, M] type syntax with Python rules regarding negative integers. This is parsed as an expression and can

arise from expansion or contain calculations.

Currently stepping, Ellipsis, and simultaneous multi-index extracting are not yet implemented.

There are some subtle things here with possibility of variables been passed by reference.

At 1.4 the `getnext`, `scanint`, `scanfunc`, `getop` chain got revisited to trigger automatic insertion of the `nil` variable if needed, without having in situations like here to define operators to support «`[:]` or «`:]»». And as we want to implement nested slicing à la NumPy, we would have had to handle also «::,» for example. Thus here we simply have to define the sole operator «::» and it will be some sort of inert joiner preparing a slicing spec.`

### 11.20.3 Macro layer implementing indexing and slicing

`xintexpr` applies slicing not only to «objects» (which can be passed as arguments to functions) but also to «oples».

Our «nlists» are not necessarily regular N-dimensional arrays à la NumPy. Leaves can be at arbitrary depths. If we were handling regular «ndarrays», we could proceed a bit differently.

For the related explanations, refer to the user manual.

Notice that currently the code uses f-expandable (and not using \expanded) macros \xintApply, \xintApplyUnbraced, \xintKeep, \xintTrim, \xintNthOne from *xinttools*.

But the whole expansion happens inside an \expanded context, so possibly some gain could be achieved with x-expandable variants (xintexpr < 1.4 had an \xintKeep:x:csv).

I coded \xintApply:x and \xintApplyUnbraced:x in *xinttools*. Brief testing indicated they were perhaps a bit better for 5x5x5x5 and 15x15x15x15 arrays of 8 digits numbers and for 30x30x15 with 16 digits numbers: say 1% gain... this seems to raise to between 4% and 5% for 400x400 array of 1 digit...

Currently sticking with old macros.

\xintNthElt from xinttools (knowingly) strips one level of braces when fetching kth «item» from
{v1}...{vN}. If we expand {\xintNthElt{k}{{v1}...{vN}}} (notice external braces):
  if k is out of range we end up with {}
  if k is in range and the kth braced item was {} we end up with {}
  if k is in range and the kth braced item was {17} we end up with {17}

```

Problem is that individual numbers such as 17 are stored {{17}}. So we must have one more brace pair and in the first two cases we end up with {{}}. But in the first case we should end up with the empty ople {}, not the empty bracketed ople {{}}.

I have thus added \xintNthOne to **xinttools** which does not strip brace pair from an extracted item.

Attention: \XINT\_nthonepy\_a does no expansion on second argument. But here arguments are either numerical or already expanded. Normally.

## 11.21 Support for raw A/B[N]

Releases earlier than 1.1 required the use of braces around A/B[N] input. The [N] is now implemented directly. \*BUT\* this uses a delimited macro! thus N is not allowed to be itself an expression (I could add it...). *\xintF*, *\xintiiE*, and *\XINTinFloatE* all put #2 in a *\numexpr*. But attention to the fact that *\numexpr* stops at spaces separating digits: *\the\numexpr 3 + 7 9\relax* gives 109 $\relax$  !! Hence we have to be careful.

*\numexpr* will not handle catcode 11 digits, but adding a *\detokenize* will suddenly make illicit for N to rely on macro expansion.

At 1.4, [ is already overloaded and it is not easy to support this. We do this by a kludge maintaining more or less former (very not efficient) way but using \$ sign which is free for time being. No, finally I use the null character, should be safe enough! (I hesitated about using R with catcode 12).

As for ? operator we needed to hack into *\XINT\_expr\_getop\_b* for intercepting that pseudo operator. See also *\XINT\_expr\_scanint\_c* (*\XINT\_expr\_rawxintfrac*).

```

At 1.4g, fix for input "x! == y" via a fake operator !=. The ! is of catcode 11 but this does not matter here. The definition of \XINT\_expr\_itself\_!= is required by the functioning of the scanop macros.

We don't have to worry about "x! = y" as the single-character Boolean comparison = operator has been removed from syntax. Fixing it would have required obeying space tokens when parsing operators. For "x! == y" case, obeying space tokens would not solve "x!=y" input case anyhow.

```

```

## 11.24 User defined variables

11.24.1 \xintdefvar, \xintdefiivar, \xintdeffloatvar . . . . .	369
11.24.2 \xintunassignvar . . . . .	373

### 11.24.1 \xintdefvar, \xintdefiivar, \xintdeffloatvar

1.1 (2014/10/28).

1.2p (2017/12/05) [commented 2017/12/01]. Extends \xintdefvar et al. to accept simultaneous assignments to multiple variables.

1.3c (2018/06/17) [commented 2018/06/17]. Use \xintexprSafeCatcodes (to palliate issue with active semi-colon from Babel+French if in body of a L<sup>A</sup>T<sub>E</sub>X document).

And allow usage with both syntaxes `name:=expr;` or `name=expr;`. Also the colon may have catcode 11, 12, or 13 with no issue. Variable names may contain letters, digits, underscores, and must not start with a digit. Names starting with @ or an underscore are reserved.

- currently @, @1, @2, @3, and @4 are reserved because they have special meanings for use in iterations,

- `@@`, `@@@`, `@@@@` are also reserved but are technically functions, not variables: a user may possibly define `@@` as a variable name, but if it is followed by parentheses, the function interpretation will be applied (rather than the variable interpretation followed by a tacit multiplication),
- since 1.21, the underscore `_` may be used as separator of digits in long numbers. Hence a variable whose name starts with `_` will not play well with the mechanism of tacit multiplication of variables by numbers: the underscore will be removed from input stream by the number scanner, thus creating an undefined or wrong variable name, or none at all if the variable name was an initial `_` followed by digits.

Note that the optional argument [P] as usable with `\xintfloatexpr` is \*\*not\*\* supported by `\xintdeffloatvar`. One must do `\xintdeffloatvar foo = \xintfloatexpr[16] blabla \relax`; to achieve the effect.

**1.4 (2020/01/31) [commented 2020/01/27].** The expression will be fetched up to final semi-colon in a manner allowing inner semi-colons as used in the `iter()`, `rseq()`, `subsm()`, `subsn()` etc... syntax. They don't need to be hidden within a braced pair anymore.

**1.4 (2020/01/31).** Automatic unpacking in case of simultaneous assignments if the expression evaluates to a ntuple.

Notes (added much later on 2021/06/10 during preparation of 1.4i):

1. the code did not try to intercept illicit syntax such as `\xintdefvar a,b,c:=<number>;`. It blindly «unpacked» the number handling it as if it was a ntuple. The extended functionality added at 1.4i requires to check for such a situation, as the syntax is not illicit anymore.
2. the code was broken in case the expression to evaluate was an ople of length 10 or more, due to a silly mistake at some point during 1.4 development which replaced some `\ifnum` by an `\i` `f`, perhaps due to mental confusion with the fact that functions can have at most 9 arguments, but here the code is about defining variables. Anyway this got fixed as corollary to the 1.4i extension.

**1.4c (2021/02/20) [commented 2021/02/20].** One year later I realized I had broken tacit multiplication for situations such as `variable(1+2)`. As hinted at in comments above before 1.4 release I had been doing some deep refactoring here, which I cancelled almost completely in the end... but not quite, and as a result there was a problem that some macro holding braced contents was expanded to late, once it was in old core routines of `xintfrac` not expecting other things than digits. I do an emergency bugfix here with some `\expandafter`'s but I don't have the code in my brain at this time, and don't have the luxury now to invest into it. Let's hope this does not induce breakage elsewhere, and that the February 2020 1.4 did not break something else.

**1.4e (2021/05/05) [commented 2021/04/17].**

Modifies `\xintdeffloatvar` to round to the prevailing precision (formerly, any operation would induce rounding, but in case of things such as `\xintdeffloatvar foo:=\xintexpr 1/100!\relax`; there was no automatic rounding. One could use `0+` syntax to trigger it, and for oples, some trick like `\xintfloatexpr[\XINTdigits]...\relax` extra wrapper.

**1.4g (2021/05/25) [commented 2021/05/22].**

The `\expandafter\expandafter\expandafter` et al. chain which was kept by `\XINT_expr_defvar_one_b` for expanding only at time of use the `\XINT_expr_var_foo` in `\XINT_expr_onliteral_foo` were senseless overhead added at 1.4c. This is used only for real variables, not dummy variables or fake variables and it is simpler to have the `\XINT_expr_var_foo` pre-expanded. So let's use some `\edef` here.

The `\XINT_expr_onliteral_foo` is expanded as result of action of `\XINT_expr_op_`` (or `\XINT_fexpr_op_``, `\XINT_iexpr_op_``) which itself was triggered consuming already an `\XINT_expr_put_op_first`, so its expansion has to produce tokens as expected after `\XINT_expr_put_op_first`: `<precedence token><op token>\{expanded value}`.

**1.4i (2021/06/11) [commented 2021/06/10].**

Implement extended notion of simultaneous assignments: if there are more variables than values, define the extra variables to be nil. If there are less variables than values let the last variable be defined as the ople concatenating all non reclaimed values.

If there are at least two variables, the right hand side, if it turns out to be a nutple, is (as since 1.4) automatically unpacked, then the above rules apply.

**1.4i (2021/06/11) [commented 2021/06/11].**

Fix the long-standing «seq renaming bug» via a change here of the name of auxiliary macro. Previously «onliteral\_<varname>» now «var\*\_<varname>». I hesitated with using «var\_varname\*» rather.

Hesitated adding `\XINT_expr_letvar_one` (motivation: case of simultaneous assignments leading to defining «nil» variables). Finally, no.

This SafeCatcodes is mainly in the hope that semi-colon ending the expression can still be sanitized.

Pre 1.4e definition:

```
\def\xintdeffloatvar      {\xintexprSafeCatcodes\xintdeffloatvar_a}
\def\xintdeffloatvar_a #1={\XINT_expr_defvar\xintthebarefloateval{#1}}
```

This would keep the value (or values) with extra digits, now. If this is actually wanted one can use `\xintdefvar foo:=\xintfloatexpr...\\relax;` syntax, but recalling that only operations trigger the rounding inside `\xintfloatexpr`. Some tricks are needed for no operations case if multiple or nested values. But for a single one, one can use simply the `float()` function.

```

2009 \def\xintdefvar      {\xintexprSafeCatcodes\xintdefvar_a}%
2010 \def\xintdefvar_a#1={\XINT_expr_defvar\xintthebareeval{#1}}%

2014 \def\xintdeffloatvar_a #1={\XINT_expr_defvar\xintthebareroundedfloateval{#1}}%

```

## 11.24.2 `\xintunassignvar`

**1.2e (2015/11/22).**

**1.3d (2019/01/06).** Embarrassingly I had for a long time a misunderstanding of `\ifcsname` (let's blame its documentation) and I was not aware that it chooses FALSE branch if tested control sequence has been `\let` to `\undefined`... So earlier version didn't do the right thing (and had another bug: failure to protect `\.=0` from expansion).

The `\ifcsname` tests are done in `\XINT_expr_op_` and `\XINT_expr_op_``.

**1.4i (2021/06/11).** Track `s/onliteral/var*/` change in macro names.

```

```

#### 11.25.5 Fetching a balanced expression delimited by a semi-colon

1.4. For `subsn()` leaner syntax of nested substitutions.

Will also serve to `\xintdeffunc`, to not have to hide inner semi-colons in for example an `iter()` from `\xintdeffunc`.

Adding brace removal protection for no serious reason, anyhow the `xintexpr` parsers always removes braces when moving forward, but well.

Trigger by `\romannumeral\XINT_expr_fetch_to_semicolon` upfront.

```

2155 \def\XINT_expr_fetch_to_semicolon {\XINT_expr_fetch_to_semicolon_a {} \emptyset}%
2156 \def\XINT_expr_fetch_to_semicolon_a #1#2;%
2157 {%
2158   \ifcase\XINT_isbalanced_a \relax #1#2(\xint_bye)\xint_bye
2159     \xint_dothis{\expandafter\XINT_expr_fetch_to_semicolon_c}%

2164 \def\XINT_expr_fetch_to_semicolon_b #1#2{\XINT_expr_fetch_to_semicolon_a {#2#1;} \emptyset}%
2165 \def\XINT_expr_fetch_to_semicolon_c #1#2{\xint_c_{#2#1}}%

```

### 11.25.6 Low-level support for `omit` and `abort` keywords, the `break()` function, the `n++` construct and the semi-colon as used in the syntax of `seq()`, `add()`, `mul()`, `iter()`, `rseq()`, `iterr()`, `rrseq()`, `subsm()`, `subsn()`, `ndseq()`, `ndmap()`

There is some clever play simply based on setting suitable precedence levels combined with special meanings given to op macros.

The special `!?` internal operator is a helper for `omit` and `abort` keywords in list generators.

Prior to 1.4 support for `+[`, `*[`, `..., ]+`, `]*`, had some elements here.

**The `n++` construct** 1.1 2014/10/29 did `\expandafter\.=+\xintiCeil` which transformed it into `\romannumeral0\xinticeil`, which seems a bit weird. This exploited the fact that dummy variables macros could back then pick braced material (which in the case at hand here ended being `\romannumeral0\xinticeil...}`) and were submitted to two expansions. The result of this was to provide a not value which got expanded only in the first loop of the `:_A` and following macros of `seq`, `iter`, `rseq`, etc...

Anyhow with 1.2c I have changed the implementation of dummy variables which now need to fetch a single locked token, which they do not expand.

The `\xintiCeil` appears a bit dispendious, but I need the starting value in a `\numexpr` compatible form in the iteration loops.

```
2166 \expandafter\def\csname XINT_expr_itself_++\endcsname {++}%
2167 \expandafter\def\csname XINT_expr_itself_++)\endcsname {++}%
2168 \expandafter\let\csname XINT_expr_precedence_++)\endcsname \xint_c_i
2169 \xintFor #1 in {expr,fexpr,iiexpr} \do {%
2170   \expandafter\def\csname XINT_#1_op_++)\endcsname ##1##2\relax
2171   {\expandafter\XINT_expr_foundend
2172    \expanded{{+{\XINT:N\hook:f:one:from:one:direct\xintiCeil##1}}}}%
2173 }%
2174 }%
```

**The `break()` function** `break` is a true function, the parsing via expansion of the enclosed material proceeds via `_oparen` macros as with any other function.

```
2175 \catcode`? 3
2176 \def\XINT_expr_func_break #1#2#3{#1#2{?#3}}%
2177 \catcode`? 11
2178 \let\XINT_fexpr_func_break \XINT_expr_func_break
2179 \let\XINT_iiexpr_func_break \XINT_expr_func_break
```

**The `omit` and `abort` keywords** Comments are currently undergoing reconstruction.

The mechanism is somewhat complex. The operator `!?` will fetch a dummy value `!` or `^` which is then recognized int the loops implementing the various `seq` etc... construct using dummy variables and implement `omit` and `abort`.

In May 2021 I realized that the January 2020 1.4 had broken `omit` and `abort` if used inside a `subs()`. The definition

```
\edef\XINT_expr_var_omit #1\relax !{1\string !?!}\relax !
conflicted with the 1.4 refactoring of «subs» and similar things which had replaced formerly clean-up macros (of ! and what's next, as in now defunct \def\XINT_expr_subx:_end #1!#2#3{#1} which was involved in subs mechanism, and by the way would be incompatible with multi-letter dummy variables) by usage of an \iffalse as in "\relax\iffalse\relax !" to delimitate a sub-expression, which was supposed to be clever (the "\relax !" being delimiter for dummy variables).
```

This `\iffalse` from `subs` mechanism ended up being gobbled by `omit`/`abort` thus inducing breakage.

Grabbing \relax #2! would be a fix but looks a bit dangerous, as there can be a subexpression after the omit or abort bringing its own \relax, although this is very very unlikely.

I considered to modify the dummy variables delimiter from \relax ! to \xint\_Bye ! for example but got afraid from the ramifications, as all structures handling dummy variables would have needed refactoring.

So finally things here remain unchanged and the refactoring to fix this breakage was done in \XINT\_alleexpr\_subsx (and also subsm). Done at 1.4h. See \XINT\_alleexpr\_subsx for comments.

```
2180 \edef\xintexpr_var_omit #1\relax !{1\string !?!\relax !}%
2181 \edef\xintexpr_var_abort #1\relax !{1\string !?^\relax !}%

### 11.26.1 Comments

Comments added 2020/01/16.

The mechanism for «seq» is the following. When the parser encounters «seq», which means it parsed these letters and encountered (from expansion) an opening parenthesis, the `\XINT_expr_func` mechanism triggers the «`» operator which realizes that «seq» is a pseudo-function (there is no `_func_seq`) and thus spans the `\XINT_expr_onliteral_seq` macro (currently this means however that the knowledge of which parser we are in is lost, see comments of `\XINT_expr_op_`` code). The latter will use delimited macros and parenthesis check to fetch (without any expansion), the symbolic expression `ExprSeq` to evaluate, the `Name` (now possibly multi-letter) of the variable and the expression `ExprValues` to evaluate which will give the values to assign to the dummy variable `Name`. It then positions upstream `ExprValues` suitably terminated (see next) and after it `\{{Name}\{ExprSeq\}}`. Then it inserts a second call to the «`» operator with now «seqx» as argument hence the appropriate `\{{,fl,ii}\expr_func_seqx}` macros gets executed. The general way function macros work is that first all their arguments are evaluated via a call not to `\xintbare\{{,float,ii}\eval` but to the suitable `\XINT_{expr,flexpr,iiexpr}_oparen` core macro which does almost same excepts it expects a final closing parenthesis (of course allowing nested parenthesis in-between) and stops there. Here, this closing parenthesis got positioned deliberately with a `\relax` after it, so the parser, which always after having gathered a value looks ahead to find the next operator, thinks it has hit the end of the expression and as result inserts a `\xint_c_` (i.e. `\z@`) token for precedence level and a dummy `\relax` token (place-holder for a non-existing operator). Generally speaking «func\_foo» macros expect to be executed with three parameters #1#2#3, #1 = precedence, #2 = operator, #3 = values (call it «args») i.e. the fully evaluated list of all its arguments. The special «func\_seqx» and cousins know that the first two tokens are trash and they now proceed forward, having thus lying before them upstream the values to loop over, now fully evaluated, and `\{{Name}\{ExprSeq\}}`. It then positions appropriately `ExprSeq` inside a sub-expression and after it, following suitable delimiter, `Name` and the evaluated values to assign to `Name`.

Dummy variables are essentially simply delimited macros where the delimiter is the variable name preceded by a `\relax` token and a catcode 11 exclamation point. Thus the various «subsx», «seqx», «iterx» position the tokens appropriately and launch suitable loops.

All of this nests well, inner «seq»'s (or more often in practice «subs»'s) being allowed to refer to the dummy variables used by outer «seq»'s because the outer «seq»'s have the values to assign to their variables evaluated first and their `ExprSeq` evaluated last. For inner dummy variables to be able to refer to outer dummy variables the author must be careful of course to not use in the implementation braces { and } which would break dummy variables to fetch values beyond the closing brace.

The above «seq» mechanism was done around June 15-25th 2014 at the time of the transition from 1.09n to 1.1 but already in October 2014 I made a note that I had a hard time to understand it again:

« [START OF YEAR 2014 COMMENTS]

All of seq, add, mul, rseq, etc... (actually all of the extensive changes from `xintexpr` 1.09n to 1.1) was done around June 15-25th 2014, but the problem is that I did not document the code enough, and I had a hard time understanding in October what I had done in June. Despite the lesson, again being short on time, I do not document enough my current understanding of the innards of the beast...

I added subs, and iter in October (also the `[:n]`, `[n:]` list extractors), proving I did at least understand a bit (or rather could imitate) my earlier code (but don't ask me to explain `\xintNewExpr` !)

The `\XINT_expr_fetch_E_comma_V_equal_E_a` parses: "expression, variable=list)" (when it is called the opening ( has been swallowed, and it looks for the ending one.) Both expression and list may themselves contain parentheses and commas, we allow nesting. For example "`x^2,x=1..10`", at the end of `seq_a` we have `\{variable\{expression\}\{list\}`, in this example `\{x\{x^2\}\{1..10\}`, or more complicated "`seq(add(y,y=1..x),x=1..10)`" will work too. The variable is a single lowercase Latin letter.

The complications with `\xint_c_ii^v` in `seq_f` is for the recurrent thing that we don't know in what type of expressions we are, hence we must move back up, with some loss of efficiency (super-

fluous check for minus sign, etc...). But the code manages simultaneously *expr*, *flexpr* and *iexpr*.

[END OF YEAR 2014 OLD COMMENTS]»

On Jeudi 16 janvier 2020 à 15:13:32 I finally did the documentation as above.

The case of «*iter*», «*rseq*», «*iterr*», «*rrseq*» differs slightly because the initial values need evaluation. This is done by genuine functions *\XINT\_<parser>\_func\_iter* etc... (there was no *\XINT\_<parser>\_func\_seq*). The trick is via the semi-colon ; which is a genuine operator having the precedence of a closing parenthesis and whose action is only to stop expansion. Thus this first step of gathering the initial values is done as part of the regular expansion job of the parser not using delimited macros and the ; can be hidden in braces {} because the three parsers when moving forward remove one level of braces always. Thus *\XINT\_<parser>\_func\_seq* simply hand over to *\XINT\_allexpr\_iter* which will then trigger the fetching without expansion of *ExprIter*, *Name=ExprValues* as described previously for «*seq*».

With 1.4, multi-letter names for dummy variables are allowed.

Also there is the additional 1.4 ambition to make the whole thing parsable by *\xintNewExpr*/*\xintdeffunc*. This is done by checking if all is numerical, because the *omit*, *abort* and *break()* mechanisms have no translation into macros, and the only solution for symbolic material is to simply keep it as is, so that expansion will again activate the *xintexpr* parsers. At 1.4 this approach is fine although the initial goals of *\xintNewExpr*/*\xintdeffunc* was to completely replace the parsers (whose storage method hit the string pool formerly) by macros. Now that 1.4 does not impact the string pool we can make *\xintdeffunc* much more powerful but it will not be a construct using only *xintfrac* macros, it will still be partially the *\xintexpr* etc... parsers in such cases.

Got simpler with 1.2c as now the dummy variable fetches an already encapsulated value, which is anyhow the form in which we get it.

Refactored at 1.4 using *\expanded* rather than *\csname*.

And support for multi-letter variables, which means function declarations can now use multi-letter variables !

### 11.26.2 *subs()*: substitution of one variable

```
2248 \def\XINT_expr_onliteral_subs
2249 {%
2250   \expandafter\XINT_allexpr_subs_f
2251   \romannumeral`&&@\XINT_expr_fetch_E_comma_V_equal_E_a {}%
2252 }%
2253 \def\XINT_allexpr_subs_f #1#2{\xint_c_ii^v `{subsx}#2)\relax #1}%
2254 \def\XINT_expr_func_subsx #1#2{\XINT_allexpr_subsx \xintbareeval }%
2255 \def\XINT_flexpr_func_subsx #1#2{\XINT_allexpr_subsx \xintbarefloateval}%
2256 \def\XINT_iexpr_func_subsx #1#2{\XINT_allexpr_subsx \xintbareiieval }%
```

#2 is the value to assign to the dummy variable #3 is the dummy variable name (possibly multi-letter), #4 is the expression to evaluate

1.4 was doing something clever to get rid of the ! and tokens following it, via an *\iffalse...\\fi* which erased them and propagated the expansion to trigger the getopt:

*\expanded\bgroup\romannumeral0#1#4\relax \iffalse\relax !#3{#2}{\fi\expandafter}*

But sadly, with a delay of more than one year later (right after having released 1.4g) I realized that this had broken *omit* and *abort* if inside a *subs*. As *omit* and *abort* would clean all up to *\relax* !, this meant here swallowing in particular the above *\iffalse*, leaving a dangling *\fi*. I had the files which show this bug already at time of 1.4 release but did not compile them, and they were not included in my test suite.

I hesitated with modifying the delimiter from "*\relax !<varname>*" (catcode 11 !) to "*\relax \xint\_Bye<varname>*" for the dummy variables which would have allowed some trickery using

\xint\_Bye... \xint\_bye clean-up but got afraid from the breakage potential of such refactoring with many induced changes.

A variant like this:

```
\def\xINT_alleexpr_subsx #1#2#3#4
{
    \expandafter\xINT_expr_clean_and_put_op_first
    \expanded
    {\romannumeral0#1#4\relax !#3{#2}\xint:\expandafter}\romannumeral`&&\XINT_expr_getop
}
```

```
\def\xINT_expr_clean_and_put_op_first #1#2\xint:#3#4{#3#4{#1}}
```

breaks nesting: the braces make variables encountered in #4 unable to match their definition. This would work:

```
\def\xINT_alleexpr_subsx #1#2#3#4
{
    \expandafter\xINT_alleexpr_subsx_clean\romannumeral0#1#4\relax !#3{#2}\xint:
}
\def\xINT_alleexpr_subsx_clean #1#2\xint:
{
    \expandafter\xINT_expr_put_op_first
    \expanded{\unexpanded{{#1}}\expandafter}\romannumeral`&&@\XINT_expr_getop
}
```

(not tested).

But in the end I decided to simply fix the first envisioned code above. This accepts expansion of supposedly inert #3{#2}. There is again the \iffalse but it is moved to the right. This change limits possibly hacky future developments. Done at 1.4h (2021/01/27).

No need for the \expandafter's from \XINT\_expr\_put\_op\_first in \XINT\_expr\_clean\_and\_put\_op\_first.

```
2257 \def\xINT_alleexpr_subsx #1#2#3#4%
2258 {%
2259     \expandafter\xINT_expr_clean_and_put_op_first
2260     \expanded
2261     \bgroup\romannumeral0#1#4\relax !#3{#2}\xint:\iffalse{\fi\expandafter}%
2262     \romannumeral`&&@\XINT_expr_getop
2263 }%
2264 \def\xINT_expr_clean_and_put_op_first #1#2\xint:#3#4{#3#4{#1}}%
```

### 11.26.3 `subsm()`: simultaneous independent substitutions

New with 1.4. Globally the var1=expr1; var2=expr2; var2=expr3;... part can arise from expansion, except that once a semi-colon has been found (from expansion) the varK= thing following it must be there. And as for `subs()` the final parenthesis must be there from the start.

```
2265 \def\xINT_expr_onliteral_subsm
2266 {%
2267     \expandafter\xINT_alleexpr_subsm_f
2268     \romannumeral`&&@\XINT_expr_fetch_E_comma_V_equal_E_a {}%
2269 }%

#### 11.26.4 `subsn()`: leaner syntax for nesting (possibly dependent) substitutions

New with 1.4. 2020/01/24

```

2307 \def\XINT_expr_onliteral_subsn
2308 {%
2309   \expandafter\XINT_alleexpr_subsn_f
2310   \romannumeral`&&@\XINT_expr_fetch_E_comma_V_equal_E_a {}%
2311 }%
2312 \def\XINT_alleexpr_subsn_f #1{\XINT_alleexpr_subsn_g #1}%
#1 = Name1
#2 = Expression in all variables which is to evaluate

```

#3 = all the stuff after `Name1 =` and up to final parenthesis  
 This one needed no reactoring at 1.4h to fix the omit/abort problem, as there was no `\iffalse..\fi`  
 clean-up: the clean-up is done directly via `\XINT_alleexpr_subsnx_J`.

I only added usage of `\XINT_expr_put_op_first_noexpand`. There may be other locations where it could be used, but I can't afford now reviewing usage. For next release after 1.4h bugfix.

```

### 11.26.6 iter()

Prior to 1.2g, the `iter` keyword was what is now called `iterr`, analogous with `rrseq`. Somehow I forgot an `iter` functioning like `rseq` with the sole difference of printing only the last iteration. Both `rseq` and `iter` work well with list selectors, as `@` refers to the whole comma separated sequence of the initial values. I have thus deliberately done the backwards incompatible renaming of `iter` to `iterr`, and the new `iter`.

To understand the tokens which are presented to `\XINT_allexpr_iter` it is needed to check elsewhere in the source code how the ; hack is done.

The #2 in `\XINT_allexpr_iter` is `\xint_c_i` from the ; hack. Formerly (`xint < 1.4`) there was no such token. The change is motivated to using ; also in `subsm()` syntax.

```

### 11.26.7 add(), mul()

Comments under reconstruction.

These were a bit anomalous as they did not implement omit and abort keyword and the break() function (and per force then neither the n++ syntax).

At 1.4 they are simply mapped to using adequately iter(). Thus, there is small loss in efficiency, but supporting omit, abort and break is important. Using dedicated macros here would have caused also slight efficiency drop. Simpler to remove the old approach.

```

2462 \def\XINT_expr_onliteral_add
2463 {\expandafter\XINT_allexpr_add_f\romannumeral`&&@\XINT_expr_fetch_E_comma_V_equal_E_a {}%}

2465 \def\XINT_expr_onliteral_mul
2466 {\expandafter\XINT_allexpr_mul_f\romannumeral`&&@\XINT_expr_fetch_E_comma_V_equal_E_a {}%}
2467 \def\XINT_allexpr_mul_f #1#2{\xint_c_ii^v `{opx}#2)\relax #1{*}{1}}%
2468 \def\XINT_expr_func_opx {\XINT:NHook:opx \XINT_allexpr_opx \xintbareeval }%
2469 \def\XINT_flexpr_func_opx {\XINT:NHook:opx \XINT_allexpr_opx \xintbarefloateval}%
2470 \def\XINT_iexpr_func_opx {\XINT:NHook:opx \XINT_allexpr_opx \xintbareiieval }%

```

1.4a In case of usage of omit (did I not test it? obviously I didn't as neither omit nor abort could work; and break neither), 1.4 code using (#6) syntax caused a (somewhat misleading) «missing )» error message which originated in the #6. This is non-obvious problem (perhaps explained why prior to 1.4 I had not added support for omit and break() to add() and mul()...).

Allowing () is not enough as it would have to be 0 or 1 depending on whether we are using add() or mul(). Hence the somewhat complicated detour (relying on precise way var\_omit and var\_abort work) via \XINT\_allexpr\_opx\_ifnotomitted.

\break() has special meaning here as it is used as last operand, not as last value. The code is very unsatisfactory and inefficient but this is hotfix for 1.4a.

### 11.26.8 rseq()

When `func_rseq` has its turn, initial segment has been scanned by `oparen`, the ; mimicking the rôle of a closing parenthesis, and stopping further expansion (and leaving a `\xint_c_i` left-over token since 1.4). The ; is discovered during standard parsing mode, it may be for example {} or arise from expansion as `rseq` does not use a delimited macro to locate it.

### 11.27.3 `ndfillraw()`

New with 1.4. 2020/01/24. J'hésite à autoriser un #1 quelconque, ou plutôt à le wrapper dans un `\xintbareval`. Mais il faut alors distinguer les trois. De toute façon les variables ne marcheraient pas donc j'hésite à mettre un wrapper automatique. Mais ce n'est pas bien d'autoriser l'injection de choses quelconques.

Pour des choses comme `ndfillraw(\xintRandomBit,[10,10])`.

Je n'aime pas le nom !. Le changer. `ndconst?` Surtout je n'aime pas que dans le premier argument il faut rajouter explicitement si nécessaire `\xintiiexpr wrap`.

```

### 11.28 Other pseudo-functions: `bool()`, `togl()`, `protect()`, `qraw()`, `qint()`, `qfrac()`, `qfloat()`, `qrand()`, `random()`, `rbit()`

bool, *togl* and *protect* use delimited macros. They are not true functions, they turn off the parser to gather their "variable".

**1.2 (2015/10/10).** Adds *qint()*, *qfrac()*, *qfloat()*.

**1.3c (2018/06/17).** Adds *qraw()*. Useful to limit impact on TeX memory from abuse of *\csname*'s storage when generating many comma separated values from a loop.

**1.3e (2019/04/05).** *qfloat()* keeps a short mantissa if possible.

They allow the user to hand over quickly a big number to the parser, spaces not immediately removed but should be harmless in general. The *qraw()* does no post-processing at all apart complete expansion, useful for comma-separated values, but must be obedient to (non really documented) expected format. Each uses a delimited macro, the closing parenthesis can not emerge from expansion.

1.3b. *random()*, *qrand()* Function-like syntax but with no argument currently, so let's use fast parsing which requires though the closing parenthesis to be explicit.

Attention that *qraw()* which pre-supposes knowledge of internal storage model is fragile and may break at any release.

1.4 adds *rbit()*. Short for random bit.

```

```

Hesitation at 1.3e about using *\XINTinFloatSdigits* and *\XINTinFloatS*. Finally I add a *sfloat()* function. It helps for *xinttrig.sty*.

```

3107 \def\xint_expr_func_float #1#2#3%
3108 {%
3109     \expandafter #1\expandafter #2\expandafter{\expandafter{%
3110     \romannumeral`&&@\XINT:NHook:f:one:and:opt:direct
3111     \XINT:expr:f:one:and:opt #3,!XINTinFloatdigits\xintFloat
3112     } }%
3113 }%
3114 \let\xint_fexpr_func_float\xint_expr_func_float

```

*float\_()* was added at 1.4, as a shortcut alias to *float()* skipping the check for an optional second argument. This is useful to transfer function definitions between *\xintexpr* and *\xint-floatexpr* contexts.

No need for a similar shortcut for *sfloat()* as currently used in *xinttrig.sty* to go from *float* to *expr*: as it is used there as *sfloat(x)* with dummy *x*, it sees there is no optional argument, contrarily to for example *float(\xintexpr...\\relax)* which has to allow for the inner expression to expand to an ople with two items, so does not know in which branch it is at time of definition.

After some hesitation at 1.4e regarding guard digits mechanism the *float\_()* got renamed to *float\_dgt()*, but then renamed back to *float\_()* to avoid a breaking change and having to document it.

Nevertheless the documentation of 1.4e mentioned `float_dgt()`... but it was still `float_()`... now changed into `float_dgt()` for real at 1.4f.

1.4f also adds private `float_dgtormax` and `sfloat_dgtormax` for matters of *xinttrig*.

## 11.30 User declared functions

It is possible that the author actually does understand at this time the `\xintNewExpr`/`\xintdeffunc` refactored code and mechanisms for the first time since 2014: past evolutions such as the 2018 1.3 refactoring were done a bit in the fog (although they did accomplish a crucial step).

The 1.4 version of function and macro definitions is much more powerful than 1.3 one. But the mechanisms such as «`omit`», «`abort`» and «`break()`» in `iter()` et al. can't be translated into much else than their actual code when they potentially have to apply to non-numeric only context. The 1.4 `\xintdeffunc` is thus apparently able to digest them but its pre-parsing benefits are limited compared to simply assigning such parts of an expression to a mock-function created by `\xintNewFunction` (which creates simply a TeX macro from its substitution expression in macro parameters and add syntactic sugar to let it appear to `\xintexpr` as a genuine «function» although nothing of the syntax has really been pre-parsed.)

At 1.4 fetching the expression up to final semi-colon is done using `\XINT_expr_fetch_to_semicolon`, hence semi-colons arising in the syntax do not need to be hidden inside braces.

11.30.1 `\xintdeffunc`, `\xintdefiifunc`, `\xintdeffloatfunc` . . . . . 411

11.30.2	\xintdefufunc, \xintdefiifunc, \xintdeffloatfunc . . . . .	414
11.30.3	\xintunassignexprfunc, \xintunassigniexprfunc, \xintunassignfloatexprfunc .	415
11.30.4	\xintNewFunction . . . . .	416
11.30.5	Mysterious stuff . . . . .	417
11.30.6	\XINT_expr_redefinemacros . . . . .	429
11.30.7	\xintNewExpr, \xintNewIExpr, \xintNewFloatExpr, \xintNewIIExpr . . . . .	430
11.30.8	\ifxintexprsafecatcodes, \xintexprSafeCatcodes, \xintexprRestoreCatcodes .	432

**11.30.1 \xintdefufunc, \xintdefiifunc, \xintdeffloatfunc****1.2c (2015/11/16) [commented 2015/11/12].**

Note: it is possible to have same name assigned both to a variable and a function: things such as `add(f(f), f=1..10)` are possible.

**1.2c (2015/11/16) [commented 2015/11/13].**

Function names first expanded then detokenized and cleaned of spaces.

**1.2e (2015/11/22) [commented 2015/11/21].**

No \detokenize anymore on the function names. And #1(#2)#3=#4 parameter pattern to avoid to have to worry if a : is there and it is active.

**1.2f (2016/03/12) [commented 2016/02/22].**

La macro associée à la fonction ne débute plus par un \roman numeral, car de toute façon elle est pour emploi dans \csname..\endcsname.

**1.2f (2016/03/12) [commented 2016/03/08].**

Comma separated expressions allowed (formerly this required using parenthesis \xintdeffunc `foo(x,...):=(..., ..., ...)`;

**1.3c (2018/06/17) [commented 2018/06/17].**

Usage of \xintexprSafeCatcodes to be compatible with an active semi-colon at time of use; the colon was not a problem (see ##3) already.

**1.3e (2019/04/05).**

\xintdefefunc variant added for functions which will expand completely if used with numeric arguments in other function definitions. They can't be used for recursive definitions.

**1.4 (2020/01/31) [commented 2020/01/10].**

Multi-letter variables can be used (with no prior declaration)

**1.4 (2020/01/31) [commented 2020/01/11].**

The new internal data model has caused many worries initially (such as whether to allow functions with «ople» outputs in contrast to «numbers» or «nuptles») but in the end all is simpler again and the refactoring of ? and ?? in function definitions allows to fuse inert functions (allowing recursive definitions) and expanding functions (expanding completely if with numeric arguments) into a single entity.

Thus the 1.3e \xintdefefunc, \xintdefiifunc, \xintdeffloatfunc constructors of «expanding» functions are kept only as aliases of legacy \xintdeffunc et al. and deprecated.

A special situation is with functions of no variables. In that case it will be handled as an inert entity, else they would not be different from variables.

**1.4 (2020/01/31) [commented 2020/01/19].**

Addition de la syntaxe déclarative \xintdeffunc `foo(a,b,...,*z) = ...;`

```

Deliberate brace stripping of #3 to reveal the elements of the ople, which may be atoms i.e. numeric data such as {1}, or again oples, which means that the corresponding item was a ntuple, for example it came from input syntax such as foo(1, 2, [1, 2], 3), so (up to details of raw encoding) {1}{2}{{1}{2}}{3}, which gives 4 braced arguments to macro #2.

```
3604 \def\XINT:NHook:userinfofunc #1#2#3{#2#3\iffalse{\fi}}%
```

Here #1 indicates the number k-1 of standard positional arguments of the call signature, the kth and last one having been declared of variadic type. The braces around \xintTrim{#1}{#4} have the effect to gather all these remaining elements to provide a single one to the TeX macro.

For example input was foo(1,2,3,4,5) and call signature was foo(a,b,\*z). Then #4 will fetch {{1}{2}{3}{4}{5}}, with one level of brace removal. We will have \xintKeep{2}{{1}{2}{3}{4}{5}} which produces {1}{2}. Then {\xintTrim{2}{{1}{2}{3}{4}{5}}} which produces {{3}{4}{5}}. So the macro will be used as \macro{1}{2}{{3}{4}{5}} having been declared as a macro with 3 arguments.

The above comments were added in June 2021 but the code was done on January 19, 2020 for 1.4.

Note on June 10, 2021: at core level `\XINT_NewFunc` is used which is derived from `\XINT_NewExpr` which has always prepared TeX macros with non-delimited parameters. A refactoring could add a final delimiter, for example `\relax`. The macro with 3 arguments would be defined as `\def\macro#1#2#3\relax{...}` for example. Then we could transfer to TeX core processing what is achieved here via `\xintKeep`/`\xintTrim`, of course adding efficiency, via insertion of the delimiter. In the case of `foo(1,2,3,4,5)` we would have the #3 of delimited `\macro` fetch `{3}{4}{5}`, no brace removal, which is equivalent to current situation fetching `{3}{4}{5}` with brace removal. But let's see in case of `foo(1,2,3)` then. This would lead to delimited `\macro{1}{2}{3}\relax` and #3 will fetch `{3}`, removing one brace pair. Whereas current non-delimited `\macro` is used as `\macro{1}{2}{3}` from the Keep/Trim, then #3 fetches `{3}`, removing one brace pair. Not the same thing. So it seems there is a stumbling-block here to adopt such an alternative method, in relation with brace removal. Rather relieved in fact, as my head starts spinning in ople world. Seems better to stop thinking about doing something like that, and what it would imply as consequences for user declarative interface also. Opes are dangerous to mental health, let's stick with one-ples: « named arguments in function body declaration must stand for one-ples », even the last one, although a priori it could be envisioned if `foo` has been declared with call signature `(x,y,z)` and is used with more items that `z` is mapped to the ople of extra elements beyond the first two ones. For my sanity I stick with my January 2020 concept of `(x,y,*z)` which makes `z` stand for a nutple always and having to be used as such in the function body (possibly unpacked there using `*z`).

#### 11.30.4 \xintNewFunction

1.2h (2016/11/20). Syntax is `\xintNewFunction{<name>}[nb of arguments]{expression with #1, #2, ... as in \xintNewExpr}`. This defines a function for all three parsers but the expression parsing is delayed until function execution. Hence the expression admits all constructs, contrarily to `\xintNewExpr` or `\xintdeffunc`.

As the letters used for variables in `\xintdeffunc`, #1, #2, etc... can not stand for non numeric «oples», because at time of function call  $f(a, b, c, \dots)$  how to decide if #1 stands for a or a, b etc... ? Of course «a» can be packed and thus the macro function can handle #1 as a «tuple» and for this be defined with the \* unpacking operator being applied to it.

```

### 11.30.5 Mysterious stuff

There was an *\xintNewExpr* already in 1.07 from May 2013, which was modified in September 2013 to work with the # macro parameter character, and then refactored into a more powerful version in June 2014 for 1.1 release of 2014/10/28.

It is always too soon to try to comment and explain. In brief, this attempts to hack into the *purely numeric* *\xintexpr* parsers to transform them into *symbolic* parsers, allowing to do once and for all the parsing job and inherit a gigantic nested macro. Originally only f-expandable nesting. The initial motivation was that the *\csname* encapsulation impacted the string pool memory. Later this work proved to be the basis to provide support for implementing user-defined functions and it is now its main purpose.

Deep refactorings happened at 1.3 and 1.4.

At 1.3 the crucial idea of the «hook» macros was introduced, reducing considerably the preparatory work done by *\xintNewExpr*.

At 1.4 further considerable simplifications happened, and it is possible that the author currently does at long last understand the code!

The 1.3 code had serious complications with trying to identify would-be «list» arguments, distinguishing them from «single» arguments (things like parsing *#2+[[#1..[#3]..#4][#5:#6]]\*#7* and convert it to a single nested f-exandable macro...)

The conversion at 1.4 is both more powerful and simpler, due in part to the new storage model which from *\csname* encapsulated comma separated values up to 1.3f became simply a braced list of braced values, and also crucially due to the possibilities opened up by usage of *\expanded* primitive.

```

Attention here that user function names may contain digits, so we don't use a \detokenize or ~ approach.

This syntax means that a function defined by `\xintdeffunc` never expands when used in another definition, so it can implement recursive definitions.

`\XINT:NE:userefunc` et al. added at 1.3e.

I added at `\xintdefefunc`, `\xintdefiiefunc`, `\xintdefffloatfunc` at 1.3e to on the contrary expand if possible (i.e. if used only with numeric arguments) in another definition.

The `\XINTusefunc` uses `\expanded`. Its ancestor `\xintExpandArgs` (*xinttools* 1.3) had some more primitive f-expansion technique.

### 11.30.6 *\xintexpr\_redefinemacros*

*Completely refactored at 1.3.*

Again refactored at 1.4. The availability of `\expanded` allows more powerful mechanisms and more importantly I better thought out the root problems caused by the handling of list operations in this context and this helped simplify considerably the code.

```

### 11.30.7 *\xintNewExpr*, *\xintNewIExpr*, *\xintNewFloatExpr*, *\xintNewIIExpr*

1.2c modifications to accomodate *\XINT\_expr\_deffunc\_newexpr* etc..

1.2f adds token *\XINT\_newexpr\_clean* to be able to have a different *\XINT\_newfunc\_clean*.

As *\XINT\_NewExpr* always execute *\XINT\_expr\_redefineprints* since 1.3e whether with *\xintNewExpr* or *\XINT\_NewFunc*, it has been moved from argument to hardcoded in replacement text.

NO MORE *\XINT\_expr\_redefineprints* at 1.4 ! This allows better support for *\xinteval*, *\xinttheexpr* as sub-entities inside an *\xintNewExpr*. And the «cleaning» will remove the new *\XINTfstop* (detokenized from *\meaning* output), to maintain backwards compatibility with former behaviour that created macros expand to explicit digits and not an encapsulated result.

The #2#3 in clean stands for *\noexpand\XINTfstop* (where the actual *scantoken*-ized input uses \$ originally with catcode letter as the escape character).

```

4367 \def\xintNewExpr {\XINT_NewExpr\xint_firstofone\xintexpr \XINT_newexpr_clean}%
4368 \def\xintNewFloatExpr{\XINT_NewExpr\xint_firstofone\xintfloatexpr\XINT_newexpr_clean}%
4369 \def\xintNewIExpr {\XINT_NewExpr\xint_firstofone\xintiexpr \XINT_newexpr_clean}%
4370 \def\xintNewIIExpr {\XINT_NewExpr\xint_firstofone\xintiiexpr \XINT_newexpr_clean}%
4371 \def\xintNewBoolExpr {\XINT_NewExpr\xint_firstofone\xintboolexpr \XINT_newexpr_clean}%
4372 \def\XINT_newexpr_clean #1>#2#3{\noexpand\expanded\noexpand\xintNEprinthook}%
4373 \def\xintNEprinthook#1.#2{\expanded{\unexpanded{#1.}{#2}}}%

```

1.2c for *\xintdeffunc*, *\xintdefiifunc*, *\xintdeffloatfunc*.

At 1.3, *NewFunc* does not use anymore a comma delimited pattern for the arguments to the macro being defined.

At 1.4 we use *\xintthebareeval*, whose meaning now does not mean unlock from csname but *firstofone* to remove a level of braces This is involved in functioning of *expr:userfunc* and *expr:userefunc*

```

4374 \def\XINT_NewFunc {\XINT_NewExpr\xint_gobble_i\xintthebareeval\XINT_newfunc_clean}%
4375 \def\XINT_NewFloatFunc{\XINT_NewExpr\xint_gobble_i\xintthebarefloateval\XINT_newfunc_clean}%
4376 \def\XINT_NewIIFunc {\XINT_NewExpr\xint_gobble_i\xintthebareiieval\XINT_newfunc_clean}%
4377 \def\XINT_newfunc_clean #1>{}%

```

1.2c adds optional logging. For this needed to pass to *\_NewExpr\_a* the macro name as parameter.

Up to and including 1.2c the definition was global. Starting with 1.2d it is done locally.

Modified at 1.3c so that *\XINT\_NewFunc* et al. do not execute the *\xintexprSafeCatcodes*, as it is now already done earlier by *\xintdeffunc*.

```

4378 \def\XINT_NewExpr #1#2#3#4#5[#6]%

4393 #1\xintexprSafeCatcodes
4394 \XINT_expr_redefinemacros
4395 \XINT_NewExpr_a #1#2#3#4%
4396 }%

```

1.2d's `\xintNewExpr` makes a local definition. In earlier releases, the definition was global. `\the\toks0` inserts the `\endgroup`, but this will happen after `\XINT_tmpa` has already been expanded...

The `%1` is `\xint_firstofone` for `\xintNewExpr`, `\xint_gobble_i` for `\xintdeffunc`.

Attention that at 1.4, there might be entire sub-xintexpressions embedded in detokenized form. They are re-tokenized and the main thing is that the parser should not mis-interpret catcode 11 characters as starting variable names. As some macros use `:` in their names, the retokenization must be done with `:` having catcode 11. To not break embedded non-evaluated sub-expressions, the `\XINT_expr_getop` was extended to intercept the `:` (alternative would have been to never inject any macro with `:` in its name... too late now). On the other hand the `!` is not used in the macro names potentially kept as is non expanded by the `\xintNewExpr/\xintdeffunc` process; it can thus be retokenized with catcode 12. But the «hooks» of `seq()`, `iter()`, etc... if deciding they can't evaluate immediately will inject a full sub-expression (possibly arbitrarily complicated) and append to it for its delayed expansion a catcode 11 `!` character (as well as possibly catcode 3 `~` and `?` and catcode 11 caret `^` and even catcode 7 `&`). The macros `\XINT_expr_tilde` etc... below serve for this injection (there are \*two\* successive `\scantokens` using different catcode regimes and these macros remain detokenized during the first pass!) and as consequence the final meaning may have characters such as `!` or and special catcodes depending on where they are located. It may thus not be possible to (easily) retokenize the meaning as printed in the log file if `\xintverbosetrue` was issued.

If a defined function is used in another expression it would thus break things if its meaning was included pre-expanded ; a mechanism exists which keeps only the name of the macro associated to the function (this name may contain digits by the way), when the macro can not be immediately fully expanded. Thus its meaning (with its possibly funny catcodes) is not exposed. And this gives opportunity to pre-expand its arguments before actually expanding the macro.

12.22	Final clean-up . . . . .	456

A preliminary implementation was done only late in the development of `\xintexpr`, as an example of the high level user interface, in January 2019. In March and April 2019 I improved the algorithm for the inverse trigonometrical functions and included the whole as a new `\xintexpr` module. But, as the high level interface provided no way to have intermediate steps executed with guard digits, the whole scheme could only target say P-2 digits where P is the prevailing precision, and only with a moderate requirement on what it means to have P-2 digits about correct.

Finally in April 2021, after having at long last added exponential and logarithm up to 62 digits and at a rather strong precision requirement (something like, say with inputs in normal ranges: targeting at most 0.505ulp distance to exact result), I revisited the code here.

We keep most of the high level usage of `\xintdeffloatfunc`, but hack into its process in order to let it map the 4 operations and some functions such as square-root to macros using 4 extra digits. This hack is enough to support the used syntax here, but is not usable generally. All functions and their auxiliaries defined during the time the hack applies are named with `@` as first letter.

Later the public functions, without the `@`, are defined as wrappers of the `@`-named ones, which float-round to P digits on output.

Apart from that the sine and cosine series were implemented at macro level, bypassing the `\xintdeffloatfunc` interface. This is done mainly for handling Digits at high value (24 or more) as it then becomes beneficial to float-round the variable to less and less digits, the deeper one goes into the series.

And regarding the arcsine I modified a bit my original idea in order to execute the first step in a single `\numexpr`. It turns out that for 16 digits the algorithm then ``only'' needs one sine and one cosine evaluation (and a square-root), and there is no need for an arcsine series auxiliary then. I am aware this is by far not the ``best'' approach but the problem is that I am a bit enamored into the idea of the algorithm even though it is at least twice as costly than a sine evaluation! Actually, for many digits, it turns out the arcsine is less costly than two random sine evaluations, probably because the latter have the overhead of range reduction.

Speaking of this, the range reduction is rather naive and not extremely ambitious. I wrote it initially having only `sind()` and `cosd()` in mind, and in 2019 reduced degrees to radians in the most naive way possible. I have only slightly improved this for this 1.4e 2021 release, the announced precision for inputs less than say `1e6`, but at `1e8` and higher, one will start feeling the gradual loss of precision compared to the task of computing the exact mathematical result correctly rounded. Also, I do not worry here about what happens when the input is very near a big multiple of  $\pi$ , and one computes a sine for example. Maybe I will improve in future this aspect but I decided I was seriously running out of steam for the 1.4e release.

As commented in `xintlog` regarding exponential and logarithms, even though we have instilled here some dose of lower level coding, the whole suffers from `xintfrac` not yet having made floating point numbers a native type. Thus inefficiencies accumulate...

At 8 digits, the gain was only about 40% compared to 16 digits. So at the last minute, on the day I was going to do the release I decided to implement a poorman way for sine and cosine, for "speed". I transferred the idea from the arcsine `numexpr` to sine and cosine. Indeed there is an interesting speed again of about 4X compared to applying the same approach as for higher values of Digits. Correct rounding during random testing is still obtained reasonably often (at any rate more than 95% of cases near 45 degrees and always faithful rounding), although at less than the 99% reached for the main branch handling Digits up to 62. But the precision is more than enough for usage in plots for example. I am keeping the guard digits, as removing then would add a further speed gain of about 20% to 40% but the precision then would drop dramatically, and this is not acceptable at the time of our 2021 standards (not a period of enlightenment generally speaking, though).

51 \def\xintreloadxinttrig{\input xinttrig.sty }%
```

## 12.5 Auxiliary variables

The variables with private names have extra digits. Whether private or public, the variables can all be redefined without impacting the defined functions, whose meanings will contain already the variable values.

Formerly variables holding the  $1/n!$  were defined, but this got removed at 1.4e.

### 12.5.1 @twoPi, @threePiover2, @Pi, @Piover2

At 1.4e we need more digits, also *\xintdeffloatvar* changed and always rounds to P=Digits precision so we use another path to store values with extra digits.

```

52 \xintdefvar @twoPi :=
53     float(
54 6.2831853071795864769252867665590057683943387987502116419498891846156328125724180
55     ,\XINTdigitsormax+4);%
56 \xintdefvar @threePiover2 :=
57     float(
58 4.7123889803846898576939650749192543262957540990626587314624168884617246094293135
59     ,\XINTdigitsormax+4);%
60 \xintdefvar @Pi :=
61     float(
62 3.1415926535897932384626433832795028841971693993751058209749445923078164062862090
63     ,\XINTdigitsormax+4);%
64 \xintdefvar @Piover2 :=
65     float(
66 1.5707963267948966192313216916397514420985846996875529104874722961539082031431045
67     ,\XINTdigitsormax+4);%
```

### 12.5.2 @oneDegree, @oneRadian

Those are needed for range reduction, particularly @oneRadian. We define it with 12 extra digits. But the whole process of range reduction in radians is very naive one.

```

68 \xintdefvar @oneDegree :=
69     float(
70 0.017453292519943295769236907684886127134428718885417254560971914401710091146034494
71     ,\XINTdigitsormax+4);%
72 \xintdefvar @oneRadian :=
73     float(
74 57.295779513082320876798154814105170332405472466564321549160243861202847148321553
75     ,\XINTdigitsormax+12);%
```

## 12.6 Hack *\xintdeffloatfunc* for inserting usage of guard digits

1.4e. This is not a general approach, but it sufficient for the limited use case done here of *\xintdeffloatfunc*. What it does is to let *\xintdeffloatfunc* hardcode usage of macros which will execute computations with an elevated number of digits. But for example if  $5/3$  is encountered in a float expression it will remain unevaluated so one would have to use alternate input syntax for efficiency (*\xintexpr float(5/3,\xinttheDigits+4)\relax* as a subexpression, for example).

```

## 12.7 The sine and cosine series

Old pending question: should I rather use successive divisions by  $(2n+1)(2n)$ , or rather multiplication by their precomputed inverses, in a modified Horner scheme ? The \ifnum tests are executed at time of definition.

Update at last minute: this is actually exactly what I do if Digits is at most 8.

Small values of the variable are very badly handled here because a much shorter truncation of the series should be used.

At 1.4e the original `\xintdeffloatfunc` was converted into macros, whose principle can be seen also at work in `xintlog.sty`. We prepare the input variables with shorter and shorter mantissas for usage deep in the series.

This divided by about 3 the execution cost of the series for P about 60.

Originally, the thresholds were computed a priori with 0.79 as upper bound of the variable, but then for 1.4e I developed enough test files to try to adjust heuristically with a target of say 99,5% of correct rounding, and always at most 1ulp error. The numerical analysis is not easy due to the complications of the implementation...

Also, random testing never explores the weak spots...

The 0.79 (a bit more than  $\pi/4$ ) upper bound induces a costly check of variable on input, if Digits is big. Much faster would be to check if input is less than 10 degrees or 1 radian as done in xfp. But using enough coefficients for allowing up to 1 radian, which is without pain for Digits=16 starts being annoying for higher values such as Digits=48.

But the main reason I don't do it now is that I spend too much time fine-tuning the table of thresholds... maybe in next release.

### 12.7.1 Support macros for the sine and cosine series

Computing the  $1/n!$  from  $n!$  then inverting would require costly divisions and significantly increase the loading time.

So a method is employed to simply divide by  $2k(2k-1)$  or  $(2k+1)(2k)$  step by step, with what we hope are enough 8 security digits, and reducing the sizes of the mantissas at each step.

This whole section is conditional on Digits being at least nine.

```

## 12.8 Range reduction for sine and cosine using degrees

As commented in the package introduction, Range reduction is a demanding domain and we handle it semi-satisfactorily. The main problem is that in January 2019 I had done only support for degrees, and when I added radians I used the most naive approach. But one can find worse: in 2019 I was surprised to observe important divergences with Maple's results at 16 digits near  $-\pi$ . Turns out that Maple probably adds  $\pi$  in the floating point sense causing catastrophic loss of digits when one is near  $-\pi$ . On the other hand even though the approach here is still naive, it behaves much better.

The `@sind_rr()` and `@cosd_rr()` sine and cosine "doing range reduction" are coded directly at macro level via `\xintSind` and `\xintCosd` which will dispatch to usage of the sine or cosine series, depending on case.

Old note from 2019: attention that `\xintSind` and `\xintCosd` must be used with a positive argument.

We start with an auxiliary macro to reduce modulo 360 quickly.

### 12.8.1 Low level modulo 360 helper macro `\XINT_mod_ccclx_i`

**input:** `\the\numexpr\XINT_mod_ccclx_i k.N.` (delimited by dots)  
**output:** ( $N$  times  $10^k$ ) modulo 360. (with a final dot)  
Attention that  $N$  must be non-negative (I could make it accept negative but the fact that `numexpr` / is not periodical in numerator adds overhead).

360 divides 9000 hence  $10^k$  is 280 for  $k$  at least 3 and the additive group generated by it modulo 360 is the set of multiples of 40.

```
309 \def\XINT_mod_ccclx_i #1.%  
310 {  
311     \expandafter\XINT_mod_ccclx_e\the\numexpr  
312     \expandafter\XINT_mod_ccclx_j\the\numexpr1\ifcase#1 \or0\or00\else000\fi.%  
313 }%  
314 \def\XINT_mod_ccclx_j 1#1.#2.%  
315 {  
316     (\XINT_mod_ccclx_ja {++}#2#1\XINT_mod_ccclx_jb 0000000\relax  
317 }%  
318 \def\XINT_mod_ccclx_ja #1#2#3#4#5#6#7#8#9%  
319 {  
320     #9+#8+#7+#6+#5+#4+#3+#2\xint_firstoftwo{+\XINT_mod_ccclx_ja{+#9+#8+#7}}{#1}%  
321 }%  
322 \def\XINT_mod_ccclx_jb #1\xint_firstoftwo#2#3{#1+0)*280\XINT_mod_ccclx_jc #1#3}%
```

Attention that `\XINT_ccclx_e` wants non negative input because `numexpr` division is not periodical ...

```
323 \def\XINT_mod_ccclx_jc  +#1+#2+#3#4\relax{+80*(#3+#2+#1)+#3#2#1.}%  
324 \def\XINT_mod_ccclx_e#1.{\expandafter\XINT_mod_ccclx_z\the\numexpr(#1+180)/360-1.#1.}%  
325 \def\XINT_mod_ccclx_z#1.#2.{#2-360*#1.}%
```

### 12.8.2 `@sind_rr()` function and its support macro `\xintSind`

```
326 \def\XINT_flexpr_func_@sind_rr #1#2#3%  
327 {  
328     \expandafter #1\expandafter #2\expandafter{  
329     \romannumeral`&&@\XINT:N\hook:f:one:from:one{\romannumeral`&&@\xintSind#3}}%  
330 }%
```

old comment: Must be f-expandable for nesting macros from \xintNewExpr

This is where the prize of using the same macros for two distinct use cases has serious disadvantages. The reason of Digits+12 is only to support an input which contains a multiplication by @oneRadian with its extended digits.

Then we do a somewhat strange truncation to a fixed point of fractional digits, which is ok in the "Degrees" case, but causes issues of its own in the "Radians" case. Please consider this whole thing as marked for future improvement, when times allows.

**ATTENTION \xintSind ONLY FOR POSITIVE ARGUMENTS**

## 12.9 @sind(), @cosd()

The -45 is stored internally as -45/1[0] from the action of the unary minus operator, which float macros then parse faster. The 45e0 is to let it become 45[0] and not simply 45.

Here and below the `\ifnum\XINTdigits>8 45\else60\fi` will all be resolved at time of definition. This is the charm and power of expandable parsers!

```

498 \xintdeffloatfunc @sind(x) := (x)%%
499             {(x>=\ifnum\XINTdigits>8 45\else60\fi)?%

## 12.10 @sin(), @cos()

For some reason I did not define sin() and cos() in January 2019 ??

The sub `\xintexpr x*@oneRadian\relax` means that the multiplication will be done exactly @on-Radian having its 12 extra digits (and x its 4 extra digits), before being rounded in entrance of `\xintSind`, respectively `\xintCosd`, to P+12 mantissa.

The strange 79e-2 could be 0.79 which would give 79[-2] internally too.

```
520 \xintdeffloatfunc @sin(x):= (abs(x)<\ifnum\XINTdigits>8 79e-2\else1e0\fi)?  
521 { @sin_series(x) }  
522 { (x)??  
523 { -@sind_rr(-\xintexpr x*@oneRadian\relax) }  
524 { 0 }  
525 { @sind_rr(\xintexpr x*@oneRadian\relax) }  
526 }  
527 ;%  
528 \xintdeffloatfunc @cos(x):= (abs(x)<\ifnum\XINTdigits>8 79e-2\else1e0\fi)?  
529 { @cos_series(x) }  
530 { @cosd_rr(abs(\xintexpr x*@oneRadian\relax)) }  
531 ;%
```

## 12.11 @sinc()

Should I also consider adding  $(1-\cos(x))/(x^2/2)$  ? it is  $\text{sinc}^2(x/2)$  but avoids a square.

```
532 \xintdeffloatfunc @sinc(x):= (abs(x)<\ifnum\XINTdigits>8 79e-2\else1e0\fi) ?  
533 { @sin_aux(sqr(x)) }  
534 { @sind_rr(\xintexpr abs(x)*@oneRadian\relax)/abs(x) }  
535 ;%
```

## 12.12 @tan(), @tand(), @cot(), @cotd()

The 0 in cot(x) is a dummy place holder. We don't have a notion of Inf yet.

```
536 \xintdeffloatfunc @tand(x):= @sind(x)/@cosd(x);%  
537 \xintdeffloatfunc @cotd(x):= @cosd(x)/@sind(x);%  
538 \xintdeffloatfunc @tan(x) := (x)??  
539 { (x)<\ifnum\XINTdigits>8 79e-2\else1e0\fi)?  
540 { @sin(x)/@cos(x) }  
541 { -@cotd(\xintexpr9e1+x*@oneRadian\relax) }  
542 }  
543 }  
544 { 0e0 }  
545 { (x)<\ifnum\XINTdigits>8 79e-2\else1e0\fi)?  
546 { @sin(x)/@cos(x) }  
547 { @cotd(\xintexpr9e1-x*@oneRadian\relax) }  
548 }  
549 ;%  
550 \xintdeffloatfunc @cot(x) := (abs(x)<\ifnum\XINTdigits>8 79e-2\else1e0\fi)?  
551 { @cos(x)/@sin(x) }  
552 { (x)?? }
```

```

553           {-@tand(\xintexpr9e1+x*@oneRadian\relax)}
554           {0}
555           {@tand(\xintexpr9e1-x*@oneRadian\relax)}
556       }%;
```

### 12.13 @sec(), @secd(), @csc(), @cscd()

```

557 \xintdeffloatfunc @sec(x) := inv(@cos(x));%
558 \xintdeffloatfunc @csc(x) := inv(@sin(x));%
559 \xintdeffloatfunc @secd(x):= inv(@cosd(x));%
560 \xintdeffloatfunc @cscd(x):= inv(@sind(x));%
```

### 12.14 Core routine for inverse trigonometry

I always liked very much the general algorithm whose idea I found in 2019. But it costs a square root plus a sine plus a cosine all at target precision. For the arctangent the square root will be avoided by a trick. (memo: it is replaced by a division and I am not so sure now this is advantageous in fact)

And now I like it even more as I have re-done the first step entirely in a single `\numexpr...` Thus the inverse trigonometry got a serious improvement at  $1.4e...$

Here is the idea. We have  $0 < t < \sqrt{2}/2$  and we want  $a = \text{Arcsin } t$ .

Imagine we have some very good approximation  $b = a - h$ . We know  $b$ , and don't know yet  $h$ . No problem  $h$  is  $a - b$  so  $\sin(h) = \sin(a)\cos(b) - \cos(a)\sin(b)$ . And we know everything here:  $\sin(a)$  is  $t$ ,  $\cos(a)$  is  $u = \sqrt{1-t^2}$ , and we can compute  $\cos(b)$  and  $\sin(b)$ .

I said  $h$  was small so the computation of  $\sin(a)\cos(b) - \cos(a)\sin(b)$  will involve a lot of cancellation, no problem with *xint*, as it knows how to compute exactly... and if we wanted to go very low level we could do  $\cos(a)\sin(b)$  paying attention only on least significant digits.

Ok, so we have  $\sin(h)$ , but  $h$  is small, so the series of Arcsine can be used with few terms!

In fact  $h$  will be at most of the order of  $1e-9$ , so it is no problem to simply replace  $\sin(h)$  with  $h$  if the target precision is 16 !

Ok, so how do we obtain  $b$ , the good approximation to  $\text{Arcsin } t$ ? Simply by using its Taylor series, embedded in a single `\numexpr` working with nine digits numbers... I like this one! Notice that it reminisces with my questioning about how to best do Horner like for sine and cosine. Here in `\numexpr` we can only manipulate whole integers and simply can't do things such as  $\dots)*x + 5/112)*x + 3/40)*x + 1/6)*x + 1 \dots$ . But I found another way, see the code, which uses extensively the "scaling" operations in `\numexpr`.

I have not proven rigorously that  $b-a$  is always less or equal in absolute value than  $1e-9$ , but it is possible for example in Python to program it and go through all possible (less than)  $1e9$  inputs and check what happens.

Very small inputs will give  $b=0$  (first step is a fixed point rounding of  $t$  to nine fractional digits, so this rounding gives zero for input  $< 0.5e-9$ , others will give  $b=t$ , because the arcsine `\numexpr` will end up with  $1000000000$  (last time I checked that was for  $t$  a bit less than  $5e-5$ , the latter gives  $1000000001$ ). All seems to work perfectly fine, in practice...

First we let the `@sin_aux()` and `@cos_aux()` functions be usable in exact `\xintexpr` context.

The `@asin_II()` function will be used only for  $\text{Digits} > 16$ .

812      \csname XINT_flexpr_func_inv\expandafter\endcsname
813      \csname XINT_flexpr_invfunc\endcsname

```

## 12.20 Let the functions be known to the `\xintexpr` parser

We use here `float_dgtormax` which uses the smaller of Digits and 64.

```

814 \edef\xintInFloatdigitsormax{\noexpand\XINTinFloat[\the\numexpr\XINTdigitsormax]}%
815 \edef\xintInFloatSdigitsormax{\noexpand\XINTinFloatS[\the\numexpr\XINTdigitsormax]}%
816 \xintFor #1 in {sin, cos, tan, sec, csc, cot,
817                  asin, acos, atan}\do
818 {%
819     \xintdeffloatfunc #1(x) := float_dgtormax(@#1(x));%
820     \xintdeffloatfunc #1d(x) := float_dgtormax(@#1d(x));%
821     \xintdeffunc #1(x) := float_dgtormax(\xintfloatexpr @#1(sfloat_dgtormax(x))\relax);%
822     \xintdeffunc #1d(x):= float_dgtormax(\xintfloatexpr @#1d(sfloat_dgtormax(x))\relax);%
823 }%
824 \xintFor #1 in {Arg, pArg, atan2}\do
825 {%
826     \xintdeffloatfunc #1(x, y) := float_dgtormax(@#1(x, y));%
827     \xintdeffloatfunc #1d(x, y) := float_dgtormax(@#1d(x, y));%
828     \xintdeffunc #1(x, y) := float_dgtormax(\xintfloatexpr @#1(sfloat_dgtormax(x), sfloat_dgtormax(y))\relax);%
829     \xintdeffunc #1d(x, y):= float_dgtormax(\xintfloatexpr @#1d(sfloat_dgtormax(x), sfloat_dgtormax(y))\relax);%
830 }%
831 \xintdeffloatfunc sinc(x):= float_dgtormax(@sinc(x));%
832 \xintdeffunc      sinc(x):= float_dgtormax(\xintfloatexpr @sinc(sfloat_dgtormax(x))\relax);%

```

## 12.21 Synonyms: `@tg()`, `@cotg()`

These are my childhood notations and I am attached to them. In radians only, and for `\xintfloateval` only. We skip some overhead here by using a `\let` at core level.

```

833 \expandafter\let\csname XINT_flexpr_func_tg\expandafter\endcsname
834             \csname XINT_flexpr_func_tan\endcsname
835 \expandafter\let\csname XINT_flexpr_func_cotg\expandafter\endcsname
836             \csname XINT_flexpr_func_cot\endcsname

```

## 12.22 Final clean-up

Restore used dummy variables to their status prior to the package reloading. On first loading this is not needed, but I have not added a way to check here whether this is a first loading or a re-loading.

```
837 \xintdefvar twoPi := float_dgtormax(@twoPi);%
838 \xintdefvar threePiover2 := float_dgtormax(@threePiover2);%
839 \xintdefvar Pi := float_dgtormax(@Pi);%
840 \xintdefvar Piover2 := float_dgtormax(@Piover2);%
841 \xintdefvar oneDegree := float_dgtormax(@oneDegree);%
842 \xintdefvar oneRadian := float_dgtormax(@oneRadian);%
843 \xintunassignvar{@twoPi}\xintunassignvar{@threePiover2}%
844 \xintunassignvar{@Pi}\xintunassignvar{@Piover2}%
845 \xintunassignvar{@oneRadian}\xintunassignvar{@oneDegree}%
846 \xintFor* #1 in {iDTVtuwxyzX}\do{\xintrestorevariable{#1}}%
847 \XINTtrigendinput%
```

13.11.2	Log series, case III . . . . .	488

In 2019, at 1.3e release I almost included extended precision for `log()` and `exp()` but the time I could devote to *xint* expired. Finally, at long last, (and I had procrastinated far more than the two years since 2019) the 1.4e release in April 2021 brings `log10()`, `pow10()`, `log()`, `pow()` to P=Digits precision: up to 62 digits with at least (said roughly) 99% chances of correct rounding (the design is targeting less than about 0.005ulp distance to mathematical value, before rounding).

Implementation is EXPERIMENTAL.

For up to Digits=8, it is simply based upon the *poormanlog* package. The probability of correct rounding will be less than for Digits>8, especially in the cases of Digits=8 and to a lesser extent Digits=7. And, for all Digits<=8, there is a systematic loss of rounding precision in the floating point sense in the case of `log10(x)` for inputs close to 1:

Summary of limitations of `log10()` and `pow10()` in the case of Digits<=8:

- For `log10(x)` with  $x$  near 1, the precision of output as floating point will be mechanically reduced from the fact that this is based on a fixed point result, for example `log10(1.0011871)` is produced as `5.15245e-4`, which stands for 0.000515145 having indeed 9 correct fractional digits, but only 6 correct digits in the floating point sense.

This feature affects the entire range Digits<=8.

- Even if limiting to inputs  $x$  with  $1.26 < x < 10$  ( $1.26$  is a bit more than  $10^{0.1}$  hence its choice as lower bound), the *poormanlog* documentation mentions an absolute error possibly up to about  $1e-9$ . In practice a test of 10000 random inputs  $1.26 < x < 10$  revealed 9490 correctly rounded `log10(x)` at 8 digits (and the 510 non-correctly rounded ones with an error of 1 in last digit compared to correct rounding). So correct rounding achieved only in about 95% of cases here.

At 7 digits the same 10000 random inputs are correctly rounded in 99.4% of cases, and at 6 digits it is 99.94% of cases.

Again with Digits=8, the log10(i) for i in 1..1000 are all correctly rounded to 8 digits with two exceptions: log10(3) and log10(297) with a 1ulp error.

- Regarding the computation of  $10^x$ , I obtained for  $-1 < x < 1$  the following with 10000 random inputs: 518/10000 errors at 1ulp, 60/10000, and 8/10000, at respectively Digits = 8, 7, 6 so chances of correct rounding are respectively about 95%, 99.4% and more than 99.9%.

Despite its limitations the poormanlog based approach used for Digits up to 8 has the advantage of speed (at least 8X compared to working with 16 digits) and is largely precise enough for plots.

For 9 digits or more, the observed precision in some random tests appears to be at least of 99.9% chances of correct rounding, and the log10(x) with x near 1 are correctly (if not really efficiently) handled in the floating point sense for the output. The poormanlog approximate log10() is still used to boot-strap the process, generally. The pow10() at Digits=9 or more is done independently of poormanlog.

All of this is done on top of my 2013 structures for floating point computations which have always been marked as provisory and rudimentary and instills intrinsic non-efficiency:

- no internal data format for a ``floating point number at P digits'',
- mantissa lengths are again and again computed,
- digits are not pre-organized say in blocks of 4 by 4 or 8 by 8,
- floating point multiplication is done via an \*exact\* multiplication, then rounding to P digits!

This is legacy of the fact that the project was initially devoted to big integers only, but in the weeks that followed its inception in March 2013 I added more and more functionalities without a well laid out preliminary plan.

Anyway, for years I have felt a better foundation would help achieve at least something such as 2X gain (perhaps the last item by itself, if improved upon, would bring most of such 2X gain?)

I did not try to optimize for the default 16 digits, the goal being more of having a general scalable structure in place and there is no difficulty to go up to 100 digits precision if one stores extended pre-computed constants and increases the length of the ``series'' support.

Apart from log(10) and its inverse, no other logarithms are stored or pre-computed: the rest of the stored data is the same for pow10() and log10() and consists of the fractional powers  $10^{\pm 0.i}$ ,  $10^{\pm 0.0i}$ , ...,  $10^{\pm 0.00000i}$  at P+5 and also at P+10 digits.

In order to reduce the loading time of the package the inverses are not computed internally (as this would require costly divisions) but simply hard-coded with enough digits to cover the allowed Digits range.

### 13.1 Catcodes, $\varepsilon$ -**T<sub>E</sub>X** and reload detection

## 13.3 \xintreloadxintlog

Now needed at 1.4e.

```
49 \def\xintreloadxintlog{\input xintlog.sty }%
```

## 13.4 Loading the poormanlog package

Attention to the catcode regime when loading poormanlog.

As I learned the hard way (I never use my user macros), at the worst moment when wrapping up the final things for 1.3e release, \xintexprSafeCatcodes MUST be followed by some \xintexprRestoreCatcodes quickly, else next time it is used (for example by \xintdefvar) the \xintexprRestoreCatcodes will restore an obsolete catcode regime...

Also, for xintlog.sty to be multiple-times loadable, we need to avoid using LaTeX's \RequirePackage twice.

```

50 \xintexprSafeCatcodes\catcode`_ 11
51 \unless\ifdefined\XINTinFloatPowTen
```

```

52 \ifdefined\RequirePackage
53   \RequirePackage{poormanlog}%
54 \else
55   \input poormanlog.tex
56 \fi\fi
57 \xintexprRestoreCatcodes\XINTsetcatcodes

```

## 13.5 Macro layer on top of the *poormanlog* package

This was moved here with some macro renames from *xintfrac* on occasion of 1.4e release.

Breaking changes at 1.4e:

- *\poormanlog* now a no-op,
- *\xintLog* was used for *\xinteval* and differed slightly from its counterpart used for *\xintfloateval*, the latter float-rounded to  $P = \text{Digits}$ , the former did not and kept completely meaningless digits in output. Both macros now replaced by a *\PoorManLog* which will always float round the output to  $P = \text{Digits}$ . Because *xint* does not really implement a fixed point interface anyhow.
- *\xintExp* (used in *\xinteval*) and another macro (used in *\xintfloateval*) did not use a sufficiently long approximation to  $1/\log(10)$  to support precisely enough  $\exp(x)$  if output of the order of  $10^{10000}$  for example, (last two digits wrong then) and situation became worse for very high values such as  $\exp(1e8)$  which had only 4 digits correct.

The new *\PoorManExp* which replaces them is more careful... and for example  $\exp(12345678)$  obtains correct rounding ( $\text{Digits}=8$ ).

- *\XINTinFloatxintLog* and *\XINTinFloatxintExp* were removed; they were used for *log()* and *exp()* in *\xintfloateval*, and differed from *\xintLog* and *\xintExp* a bit, now renamed to *\PoorManLog* and *\PoorManExp*.

- *\PoorManPower* has simply disappeared, see *\XINTinFloatSciPow* and *\xintPow*.

See the general *xintlog* introduction for some comments on the achieved precision and probabilities of correct rounding.

### 13.5.1 *\PoorManLogBaseTen*, *\PoorManLog*

1.3f. Code originally in *poormanlog* v0.04 got transferred here. It produces the logarithm in base 10 with an error (believed to be at most) of the order of 1 unit in the 9th (i.e. last, fixed point) fractional digit. Testing seems to indicate the error is never exceeding 2 units in the 9th place, in worst cases.

These macros will still be the support macros for *\xintfloatexpr log10()*, *pow10()*, etc... up to  $\text{Digits}=8$  and the *poormanlog* logarithm is used as starting point for higher precision if  $\text{Digits}$  is at least 9.

Notice that *\PML@999999999*. expands (in *\numexpr*) to 1000000000 (ten digits), which is the only case with the output having ten digits. But there is no need here to treat this case especially, it works fine in *\PML@logbaseten*.

Breaking change at 1.4e: for consistency with various considerations on floats, the output will be float rounded to  $P=\text{Digits}$ .

One could envision the *\xinteval* variant to keep 9 fractional digits (it is known the last one may very well be off by 1 unit). But this creates complications of principles.

All of this is very strange because the logarithm clearly shows the deficiencies of the whole idea of floating point arithmetic, logarithm goes from floating point to fixed point, and coercing it into pure floating point has moral costs. Anyway, I shall oblige.

```

75 }%

```

### 13.5.2 \PoorManPowerOfTen, \PoorManExp

Originally in *poormanlog* v0.04, got transferred into *xintfrac.sty* at 1.3f, then here into *xintlog.sty* at 1.4e.

Produces  $10^x$  with 9 digits of float precision, with an error (believed to be) at most 2 units in the last place, when  $0 < x < 1$ . Of course for this the input must be precise enough to have 9 fractional digits of \*\*fixed point\*\* precision.

Breaking change at 1.4e: output always float-rounded at P=Digits.

The 1.3f definition for \xintExp (now \PoorManExp) was not careful enough (see comments above) for very large exponents. This has been corrected at 1.4e. Formerly  $\exp(12345678)$  produced shameful 6.3095734e5361659 where only the first digit (and exponent...) is correct! Now, with \xintDigits\*:=8;,  $\exp(12345678)$  will produce 6.7725836e5361659 which is correct rounding to 8 digits. Sorry if your rover expedition to Mars ended in failure due to using my software. I was not expecting anyone to use it so I did back then in 2019 a bit too expeditively the \xintExp thing on top of  $10^x$ .

The 1.4e \PoorManExpr replaces and amends deceased \xintExp.

Before using \xintRound we screen out the case of zero as \xintRound in this case outputs no fractional digits.

## 13.6 Macro support for powers

### 13.6.1 *\XINTinFloatSciPow*

This is the new name and extension of *\XINTinFloatPowerH* which was a non user-documented macro used for  $a^b$  previously, and previously was located in *xintfrac*.

A check is done whether the exponent is integer or half-integer, and if positive, the legacy *\xintFloatPower*/*\xintFloatSqrt* macros are used. The rationale is that:

- they give faster evaluations for integer exponent  $b < 10000$  (and beyond)
- they operate at any value of Digits
- they keep accuracy even with gigantic exponents, whereas the *pow10()*/*log10()* path starts losing accuracy for  $b$  about  $1e8$ . In fact at 1.4e it was even for  $b$  about  $1000$ , as *log10(A)* was not computed with enough fractional digits, except for  $0.8 < A < 1.26$  (roughly), for this usage. At the 1.4f bugfix we compute *log10(A)* with enough accuracy for  $A^b$  to be safe with  $b$  as large as  $1e7$ , and show visible degradation only for  $b$  about  $1e9$ .

The user documentation of *\xintFloatPower* mentions a 0.52 ulp(Z) error where Z is the computed result, which seems not as good as the kind of accuracy we target for *pow10()* (for  $-1 < x < 1$ ) and *log10()* (for  $1 < x < 10$ ) which is more like about 0.505ulp. Perhaps in future I will examine if I need to increase a bit the theoretical accuracy of *\xintFloatPower* but at time of 1.4e/1.4f release I have left it standing as is.

The check whether exponent is integer or half-integer is not on the value but on the representation. Even in *\xintfloatexpr*, input such  $10^{\wedge}\xintexpr4/2\relax$  is possible, and  $4/2$  will not be recognized as integer to avoid costly overhead.  $3/2$  will not be recognized as half-integer. But  $2.0$  will be recognized as integer,  $25e-1$  as half-integer.

In the computation of  $A^b$ ,  $A$  will be float-rounded to Digits, but the exponent  $b$  will be handled "as is" until last minute. Recall that the *\xintfloatexpr* parser does not automatically float round isolated inputs, this happens only once involved in computations.

In the Digits $\leq 8$  branch we do the same as for Digits $>8$  since 1.4f. At 1.4e I had strangely chosen (for "speed", but that was anyhow questionable for integer exponents less than 10 for example) to always use *log10()*/*pow10()*... But with only 9 fractional digits for the logarithms, exponents such as 1000 naturally led to last 2 or 3 digits being wrong and let's not even mention when the exponent was of the order of 1e6... now  $A^{1000}$  and  $A^{1000.5}$  are accurately computed and one can handle  $a^{1000.1}$  as  $a^{1000} \cdot a^{0.1}$ .

I wrote the code during 1.4e to 1.4f transition for doing this split of exponent automatically, but it induced a very significant time penalty down the line for fractional exponents, whereas currently  $a^b$  is computed at Digits=8 with perfectly acceptable accuracy for fractional  $\text{abs}(b) < 10$ , and at high speed, and accuracy for big exponents can be obtained by manually splitting as above (although the above has no user interface for keeping each contribution with its extra digits; a single one for  $a^h$ ,  $-1 < h < 1$ ).

At 1.4f we only need for Digits up to 8 to insert usage of `poormanlog` for non integer, non half-integer exponents. At 1.4e the code was more complicated because I had strangely opted for using always the `log10()` path. However we have to be careful to use `\PML@logbaseten` with 9 digits always.

As the legacy macros used for integer and half-integer exponents float-round the input to Digits digits, we must do the same here for coherence. Which induces some small complications here.

### 13.6.2 *\xintPow*

Support macro for  $a^b$  in *\xinteval*. This overloads the original *xintfrac* macro, keeping its original meaning only for integer exponents, which are not too big: for exact evaluation of  $A^b$ , we want the output to not have more than about 10000 digits (separately for numerator and denominator). For this we limit  $b$  depending on the length of  $A$ , simply we want  $b$  to be smaller than the rounded value of 10000 divided by the length of  $A$ . For one-digit  $A$ , this would give 10000 as maximal exponent but due to organization of code related to avoid arithmetic overflow (we can't immediately operate in *\numexpr* with  $b$  as it is authorized to be beyond TeX bound), the maximal exponent is 9999.

The criterion, which guarantees output (numerator and denominator separately) does not exceed by much 10000 digits if at all is that the exponent should be less than the (rounded in the sense of *\numexpr*) quotient of 10000 by the number of digits of  $a$  (considering separately numerator and denominator).

The decision whether to compute  $A^b$  exactly depends on the length of internal representation of  $A$ . So  $9^{9999}$  is evaluated exactly (in *\xinteval*) but for  $9.0$  it is  $9.0^{5000}$  the maximal power. This may change in future.

*1.4e* had the following bug (for  $Digits > 8$ ): big integer exponents used the *log10()*/*pow10()* based approach rather than the legacy macro path which goes via *\xintFloatPower*, as done by *\xintfloateval!* As a result powers very large integer exponents were more precise in *\xintfloateval* than in *\xinteval!*

*1.4f* fixes this. Also, it handles  $Digits \leq 8$  as  $Digits > 8$ , bringing much simplification here.

```

196 \def\xintPow{\romannumeral0\xintpow}%
197 \def\xintpow#1#2%
198 {%
199   \expandafter\xint_scipow_a\romannumeral0\xintrez{#2}\XINT_pow_int{#1}%
200 }%

```

In case of half-integer exponent the *\XINT\_scipow\_a* will have triggered usage of the (new incarnation) of *\XINTinFloatPowerH* which combines *\xintFloatPower* and square root extraction. So we only have to handle here the case of integer exponents which will trigger execution of this *\XINT\_pow\_int* macro passed as parameter to *\xintpow*.

```

201 \def\xint_pow_int #1/1[#2]%
202 {%
203   \expandafter\xint_pow_int_a\romannumeral0\XINT_dsx_addzeros{#2}#1;.%
204 }%

```

*1.4e* had a bug here for integer exponents  $\geq 10000$ : they triggered going back to the floating point routine but at a late location where the *log10()*/*pow10()* approach is used.

```

205 \def\xint_pow_int_a #1#2.%
206 {%
207   \ifnum\if-#1\xintLength{#2}\else\xintLength{#1#2}\fi>\xint_c_iv

216 `\def\XINT_pow_int_b #1.#2%`

217 {%

We now check if the output will not be too bulky. We use here (on the a of  $a^b$ ) `\xintraw`, not `\xintrez`, on purpose so that for example  $9.0^{9999}$  is computed in floating point sense but  $9^{9999}$  is computed exactly. However  $9.0^{5000}$  will be computed exactly. And if I used `\xintrez` here `\xinteval{100^2}` would print 10000.0 and `\xinteval{100^3}` would print 1.0e6. Thus situation is complex.

By the way I am happy to see that  $9.0*9.0$  in `\xinteval` does print 81.0 but the truth is that internally it does have the more bulky  $8100/1[-2]$  maybe I should make some revision of this, i.e. use rather systematically `\xintREZ` on input rather than `\xintRaw` (note taken on 2021/05/08 at time of doing 1.4f bugfix release).

218     `\expandafter\XINT_pow_int_c\romannumeral0\xintraw{#2}\xint:#1\xint:`  
219 }%

The `\XINT_fpow_fork` is (quasi top level) entry point we have found into the legacy `\xintPow` routine of `xintfrac`. Its interface is a bit weird, but let's not worry about this now.

## 13.8 End of package loading for low Digits

```
310 \ifnum\XINTdigits<9 \expandafter\XINTendxintloginput\fi%
```

## 13.9 Stored constants

The constants were obtained from Maple at 80 digits: fractional power of 10, but only one logarithm `log(10)`.

Currently the code whether for exponential or logarium will not screen out 0 digits and even will do silly multiplication by  $10^0 = 1$  in that case, and we need to store such silly values.

We add the data for the  $10^{-0.1}$  etc... because pre-computing them on the fly significantly adds overhead to the package loading.

The fractional powers of ten with  $D+5$  digits are used to compute `pow10()` function, those with  $D+10$  digits are used to compute `log10()` function. This is done with an elevated precision for two reasons: (- handling of inputs near 1, :- in order for  $a^b = \text{pow10}(b*\log10(a))$  to keep accuracy even with large exponents, say in absolute value up to  $1e7$ , degradation beginning to show-up at  $1e8$ . )

### 13.10 April 2021: at last, *\XINTinFloatPowTen*, *\XINTinFloatExp*

Done April 2021. I have procrastinated (or did not have time to devote to this) at least 5 years, even more.

Speed improvements will have to wait to long delayed refactoring of core floating point support which is still in the 2013 primitive state !

I did not try to optimize for say 16 digits, as I was more focused on reaching 60 digits in a reasonably efficient manner (trigonometric functions achieved this since 2019) in the same coding framework. Finally, up to 62 digits.

The stored constants are  $\log(10)$  at  $P+4$  digits and the powers  $10^{0.0d}, 10^{0.0d}, \dots$ , up to  $10^{0.00000d}$  for  $d=1..9$ , as well as their inverses, at  $P+5$  and  $P+10$  digits. The constants were obtained from Maple at 80 digits.

Initially I constructed the exponential series  $\exp(h)$  as one big unique nested macro. It contained pre-rounded values of the  $1/i!$  but would float-round  $h$  to various numbers of digits, with always the full initial  $h$  as input.

After having experimented with the logarithm, I redid  $\exp(h) = 1 + h(1 + h(1/2 + \dots))$  with many macros in order to have more readable code, and to dynamically cut-off more and more digits from  $h$  the deeper it is used. See the logarithm code for (perhaps) more comments.

The thresholds have been obtained from considerations including an  $h_{\max}$  (a bit more than 0.5  $\log(10) 10^{-6}$ ). Here is the table:

- maximal value of  $P$ : 8, 15, 21, 28, 35, 42, 48, 55, 62
- last included term: /1, /2, /6, /4!, /5!, /6!, /7!, /8!, /9!

Computations are done morally targeting  $P+4$  fractional fixed point digits, with a stopping criteria at say about  $5e(-P-4)$ , which was used for the table above using only the worst case. As the used macros are a mix of exact operations and floating point reductions this is in practice a bit different. The  $h$  will be initially float rounded to  $P-1$  digits. It is cut-off more and more, the deeper nested it is used.

The code for this evaluation of  $10^x$  is very poor with  $x$  very near zero: it does silly multiplication by 1, and uses more terms of exponential series than would then be necessary.

For the computation of  $\exp(x)$  as  $10^{(c*x)}$  with  $c=\log(10)^{-1}$ , we need more precise  $c$  the larger  $\text{abs}(x)$  is. For  $\text{abs}(x)<1$  (or 2), the  $c$  with  $P+4$  fractional digits is sufficient. But decimal exponents are more or less allowed to be near the TeX maximum  $2^{31}-1$ , which means that  $\text{abs}(x)$  could be as big as  $0.5e10$ , and we then need  $c$  with  $P+14$  digits to cover that range.

I am hesitating whether to first examine integral part of  $\text{abs}(x)$  and for example to use  $c$  with either  $P+4$ ,  $P+9$  or  $P+14$  digits, and also take this opportunity to inject an error message if  $x$  is too big before TeX arithmetic overflow happens later on. For time being I will use overhead of `oneoverlogt` having ample enough digits...

The exponent received as input is float rounded to  $P + 14$  digits. In practice the input will be already a  $P$ -digits float. The motivation here is for low Digits situation: but this done so that for example with `Digits=4`, we want  $\exp(12345)$  not to be evaluated as  $\exp(12350)$  which would have no meaning at all. The +14 is because we have prepared  $1/\log(10)$  with that many significant digits. This conundrum is due to the inadequation of the world of floating point numbers with `exp()` and `log()`: clearly `exp()` goes from fixed point to floating point and `log()` goes from floating point to fixed point, and coercing them to work inside the sole floating point domain is not mathematically natural. Although admittedly it does create interesting mathematical questions! A similar situation applies to functions such as `cos()` and `sin()`, what sense is there in the expression `cos(exp(50))` for example with 16 digits precision? My opinion is that it does not make ANY sense. Anyway, I shall abide.

As `\XINTinFloatS` will not add unnecessarily trailing zeros, the `\XINTdigits+14` is not really an enormous overhead for integer exponents, such as in the example above the 12345, or more realistically small integer exponents, and if the input is already float rounded to  $P$  digits, the overhead is also not enormous (float-rounding is costly when the input is a fraction).

`\XINTinfloatpowten` will receive an input with at least  $P+14$  and up to  $2P+28$  digits... fortunately with no fraction part and will start rounding it in the fixed point sense of its input to  $P+4$

digits after decimal point, which is not enormously costly.

Of course all these things pile up...

```

```

Here is how the reduction to computations of an  $\exp(h)$  via series is done.

Starting from  $x$ , after initial argument normalization, it is fixed-point rounded to 6 fractional digits giving  $x'' = \pm n.d_1\dots d_6$  (which may be 0).

I have to resist temptation using very low level routines here and wisely will employ the available user-level stuff. One computes then the difference  $x - x''$  which gives some eta, and the  $h$  will be  $\log(10).\eta$ . The subtraction and multiplication are done exactly then float rounded to  $P-1$  digits to obtain the  $h$ .

Then  $\exp(h)$  is computed. And to finish it is multiplied with the stored  $10^{\pm 0.d_1}, 10^{\pm 0.0d_2}$ , etc..., constants and its decimal exponent is increased by  $\pm n$ . These operations are done at  $P+5$  floating point digits. The final result is then float-rounded to the target  $P$  digits.

Currently I may use nested macros for some operations but will perhaps revise in future (it makes tracing very complicated if one does not have intermediate macros). The exponential series itself was initially only one single macro, but as commented above I have now modified it.

### 13.11 April 2021: at last *\XINTinFloagLogTen*, *\XINTinFloatLog*

Attention that this is not supposed to be used with *\XINTdigits* at 8 or less, it will crash if that is the case. The *log10()* and *log()* functions in case *\XINTdigits* is at most 8 are mapped to *\PoormanLogBaseTen* respectively *\PoormanLog* macros.

In the explications here I use the function names rather than the macro names.

Both *log(x)* and *log10(x)* are on top of an underlying macro which will produce *z* and *h* such that *x* is about  $10^z e^h$  (with *h* being small is obtained via a log series). Then *log(x)* computes  $\log(10)z+h$  whereas *log10(x)* computes as  $z+h/\log(10)$ .

There will be three branches [NO FINALLY ONLY TWO BRANCHES SINCE 1.4f] according to situation of *x* relative to 1. Let *y* be the math value *log10(x)* that we want to approximate to target precision *P* digits. *P* is assumed at least 9.

I will describe the algorithm roughly, but skip its underlying support analysis; at some point I mention "fixed point calculations", but in practice it is not done exactly that way, but describing it would be complicated so look at the code which is very readable (by the author, at the present time).

First we compute *z* = *+n.d\_1d\_2...d\_6* as the rounded to 6 fractional digits approximation of *y=log10(x)* obtained by first using the *poormanlog* macros on *x* (float rounded to 9 digits) then rounding as above.

Warning: this description is not in sync with the code, now the case where *d\_1d\_2...d\_6* is 000000 is filtered out and one jumps directly either to case I if *n*≠0 or to case III if *n*=0. The case when

rounding produces a z equal to zero is also handled especially.

WARNING: at 1.4f, the CASE I was REMOVED. Everything is handled as CASE II or exceptionally case III. Indeed this removal was observed to simply cost about 10% extra time at D=16 digits, which was deemed an acceptable cost. The cost is certainly higher at D=9 but also relatively lower at high D's. It means that logarithms are always computed with 9, not 4, safety \*\*fractional\*\* digits, and this allows to compute powers accurately with exponents say up to 1e7, degradation starting to show at 1e8 and for sure at 1e9. However for integer and half-integer exponents the old routine \xintFloatPower will still be used, and perhaps it will need some increased precision update as the documented 0.52ulp error bound is higher than our more stringent standards of 2021.

CASE I: [removed at 1.4f!] either n is NOT zero or d\_1d\_2...d\_6 is at least 100001. Then we compute X =  $10^{(-z)} \cdot x$  which is near 1, by using the table of powers of 10, using P+5 digits significands. Then we compute (exactly) eta = X-1, (which is in absolute value less than 0.0000012) and obtain y as  $z + \log(10)^{(-1)} \text{ times } \log(1+\eta)$  where  $\log(1+\eta) = \eta - \eta^2/2 + \eta^3/3 - \dots$  is "computed with P+4 fractional fixed point digits" [1] according to the following table:

- maximal value of P: 9, 15, 21, 27, 33, 39, 45, 51, 57, 63
- last included term: /1, /2, /3, /4, /5, /6, /7, /8, /9, /10

[1] this "P+4" includes leading fractional zeroes so in practice it will rather be done as  $\eta(1 - \eta(1/2 + \eta(1/3 - \dots)))$ , and the inner sums will be done in various precisions, the top level (external) eta probably at P-1 digits, the first inner eta at P-7 digits, the next at P-13, something in this style. The heuristics is simple: at P=9 we don't need the first inner eta, so let's use there P-9 or rather P-7 digits by security. Similarly at P=3 we would not need at all the eta, so let's use the top level one rounded at P-3+2 = P-1 digits. And there is a shift by 6 less digits at each inner level. RÉFLÉCHIR SI C'EST PAS PLUTÔT P-2 ICI, suffisant au regard de la précision par ailleurs pour la réduction près de 1.

The sequence of maximal P's is simply an arithmetic progression.

The addition of z will trigger the final rounding to P digits. The inverse of  $\log(10)$  is precomputed with P+4 digits.

This case I essentially handles x such as  $\max(x, 1/x) > 10^{0.1} = 1.2589\dots$

CASE II: n is zero and d\_1d\_2...d\_6 is not zero. We operate as in CASE I, up to the following differences:

- the table of fractional powers of 10 is used with P+10 significands.
- the X is also computed with P+10 digits, i.e. eta = X-1 (which obeys the given estimate) is estimated with P+9 [2] fractional fixed points digits and the log series will be evaluated in this sense.

- the constant  $\log(10)^{(-1)}$  is still used with only P+4 digits

The log series is terminated according to the following table:

- maximal value of P: 4, 10, 16, 22, 28, 34, 40, 46, 52, 58, 64
- last included term: /1, /2, /3, /4, /5, /6, /7, /8, /9, /10

Again the P's are in arithmetic progression, the same as before shifted by 5.

[2] same remark as above. The top level eta in  $\eta(1 - \eta(1/2 - \eta(\dots)))$  will use P+4 significant digits, but the first inner eta will be used with only P-2 digits, the next inner one with P-8 digits etc...

This case II handles the x which are near 1, but not as close as  $10^{\pm 0.000001}$ .

CASE III: z=0. In this case X = x = 1+eta and we use the log series in this sense :  $\log(10)^{(-1)} * \eta * (1 - \eta/2 + \eta^2/3 - \dots)$  where again  $\log(10)^{(-1)}$  has been precomputed with P+4 digits and morally the series uses P+4 fractional digits (P+3 would probably be enough for the precision I want, need to check my notes) and the thresholds table is:

- maximal value of P: 3, 9, 15, 21, 27, 33, 39, 45, 51, 57, 63
- last included term: /1, /2, /3, /4, /5, /6, /7, /8, /9, /10, /11

This is same progression but shifted by one.

To summarize some relevant aspects:

- this algorithm uses only  $\log(10)^{(-1)}$  as precomputed logarithm

- in particular the logarithms of small integers 2, 3, 5,... are not pre-computed. Added note: I have now tested at 16, 32, 48 and 62 digits that all of the  $\log_{10}(n)$ , for  $n = 1..1000$ , are computed with correct rounding. In fact, generally speaking, random testing of about 20000 inputs has failed to reveal a single non-correct rounding. Naturally, randomly testing is not the way to corner the software into its weak points...

- it uses two tables of fractional powers of ten: one with P+5 digits and another one with extended precision at P+10 digits.

- it needs three distinct implementations of the log series.

- it does not use the well-known trick reducing to using only odd powers in the log series (somehow I have come to dread divisions, even though here as is well-known it could be replaced with some product, my impression was that what is gained on one side is lost on the other, for the range of P I am targeting, i.e. P up to about 60.)

- all of this is experimental (in particular the previous item was not done perhaps out of sheer laziness)

Absolutely no error check is done whether the input x is really positive. As seen above the maximal target precision is 63 (not 64).

Update for 1.4f: when the logarithm is computed via case I, i.e. basically always except roughly for  $0.8 < a < 1.26$ , its fractional part has only about 4 safety digits. This is barely enough for  $a^b$  with b near 1000 and certainly not enough for  $a^b$  with b of the order 10000.

I hesitated with the option to always handle b as N+h with N integer for which we can use old *\xintFloatPower* (which perhaps I will have to update to ensure better than the 0.52ulp it mentions in its documentation). But in the end, I decided to simply add a variant where case I is handled as case II, i.e. with 9 not 4 safety fractional digits for the logarithm. This variant will be the one used by the power function for fractional exponents (non integer, non half-integer).

No check is done whether input is negative or vanishes. We apply `\XINTinfloat[9]` which if input is not zero always produces 9 digits (and perhaps a minus sign) the first digit is non-zero. This is the expected input to `\numexpr\PML@<digits><dot>.\relax`

The variants `xdg_a`, `xdg_b`, `xdg_c`, `xdg_d` were added at 1.4f to always go via II or III, ensuring more fractional digits to the logarithm for accuracy of fractional powers with big exponents. "Old" 1.4e routines were removed.

```

Here we are certain that `\xintRound{6}` produced a decimal point and 6 fractional digit tokens `#2`, but they can be zeros and also `-0.000000` is possible.

If `#1` vanishes and `#2>100000` we are in case I.

If `#1` vanishes and `100000>=#2>0` we are in case II.

If `#1` and `#2` vanish we are in case III.

If `#1` does not vanish we are in case I with a direct quicker access if `#2` vanishes.

Attention to the sign of `#1`, it is checked later on.

At 1.4f, we handle the case I with as many digits as case II (and exceptionnally case III).

```

Initially all of this was done in a single big nested macro but the float-rounding of argument to less digits worked again each time from initial long input; the advantage on the other hand was that the  $1/i$  constants were all pre-computed and rounded.

Pre-coding the successive rounding to six digits less at each stage could be done via a single loop which would then walk back up inserting coeffs like  $1/\#1$  having no special optimizing tricks. Pre-computing the  $1/\#1$  too is possible but then one would have to copy the full set of such constants (which would be pre-computed depending on P), and this will add grabbing overhead in the loop expansion. Or one defines macros to hold the pre-rounded constants.

Finally I do define macros, not only to hold the constants but to hold the whole build-up. Sacrificing brevity of code to benefit of expansion "speed".

Firts one prepares eta, with P+4 digits for mantissa, and then hands it over to the log series. This will proceed via first preparing `eta\xint:` `eta\xint:` .... `eta\xint:`, the leftmost ones being more and more reduced in number of digits. Finally one goes back up to the right, the hard-coded number of steps depending on value of `P=\XINTdigits` at time of reloading of package. This number of steps is hard-coded in the number of macros which get defined.

Descending (leftwards) chain: `_a`, Turning point: `_b`, Ascending: `_c`.

As it is very easy to make silly typing mistakes in the numerous macros I have refactored a number of times the set-up to make manual verification straightforward. Automatization is possible but the \_b macros complicate things, each one is its own special case. In the end the set-up will define then redefine some \_a and the (finally unique) \_b macro, this allows easier to read code, with no

nesting of conditionals or else branches.

Actually series III and series II differ by only a shift by and we could use always the slightly more costly series III in place of series II. But that would add one un-needed term and a bit overhead to the default P which is 16...

(1.4f: hesitation on 2021/05/09 after removal or case I log series should I not follow the simplifying logic and use always the slightly more costly III?)

### 13.11.1 Log series, case II
