

Package **mathfont** v. 1.5 Documentation  
Conrad Kosowsky  
April 2019  
`kosowsky.latex@gmail.com`

### Abstract

The **mathfont** package provides a flexible interface for changing the font of math-mode characters. The package allows the user to specify a default unicode font for each of six basic classes of Latin and Greek characters, and it provides additional support for unicode math and alphanumeric symbols, including punctuation. Crucially, **mathfont** is compatible with both X<sub>E</sub>T<sub>E</sub>X and LuaT<sub>E</sub>X, and it provides several font-loading commands that allow the user to change fonts locally or for individual characters within math mode.

For easy, “off-the-shelf” use, type the following in your document preamble and compile using X<sub>E</sub>T<sub>E</sub>X or LuaT<sub>E</sub>X:

```
\usepackage{mathfont}
\setfont{\langle font name \rangle}
```

Handling fonts in T<sub>E</sub>X and L<sup>A</sup>T<sub>E</sub>X is a notoriously difficult task. Donald Knuth originally designed T<sub>E</sub>X to support fonts created with Metafont, and while subsequent versions of T<sub>E</sub>X extended this functionality to postscript fonts, Plain T<sub>E</sub>X’s font-loading capabilities remain limited. Many, if not most, L<sup>A</sup>T<sub>E</sub>X users are unfamiliar with the .fd files that must be used in font declaration, and the minutiae of T<sub>E</sub>X’s \font primitive can be esoteric and confusing. L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub>’s New Font Selection System (NFSS) implemented a straightforward syntax for loading and managing fonts, but L<sup>A</sup>T<sub>E</sub>X macros overlaying a T<sub>E</sub>X core face the same versatility issues as Plain T<sub>E</sub>X itself. Fonts in math mode present a double challenge: even if the user successfully loads a font either in Plain T<sub>E</sub>X or through the NFSS, defining math symbols can be unintuitive for users who are unfamiliar with T<sub>E</sub>X’s \mathcode primitive. Again, L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> simplifies much of the coding challenges with its \DeclareMathSymbol macro, but from the computer’s perspective, the fundamental aspects of the task remain the same.

More recent engines such as Jonathan Kew’s X<sub>E</sub>T<sub>E</sub>X and Hans Hagen, et al.’s LuaT<sub>E</sub>X significantly extend the font-loading capabilities of T<sub>E</sub>X.<sup>1</sup> Both support TrueType and OpenType font formats and provide many additional primitives for managing fonts. The **fontspec** package by Will Robertson and Khaled Hosny acts as a front-end for the font management built into these two engines.<sup>2</sup> It allows users to easily load new fonts and transition between those ones already in memory, and users who are interested in changing text fonts should consult the documentation for that package. Notably, **fontspec** provides users with the tools

<sup>1</sup>Information on X<sub>E</sub>T<sub>E</sub>X is available at <https://tug.org/xetex/>, and information on LuaT<sub>E</sub>X is available at the official website for LuaT<sub>E</sub>X: <http://www.luatex.org/>.

<sup>2</sup>Will Robertson and Khaled Hosny, “**fontspec**—Advanced font selection in X<sub>E</sub>T<sub>E</sub>X and LuaT<sub>E</sub>X,” <https://ctan.org/pkg/fontspec>.

to manually adjust OpenType features of the fonts they load, so the package gives equivalent or in some cases superior font management capabilities to a modern WYSIWYG word processor. (Of course, the efficiency depends on the skill of the L<sup>A</sup>T<sub>E</sub>X user.) In situations where a font’s OpenType features are unclear or difficult to access, `fontspec`’s typographical advantages can significantly outweigh the accessibility of a word processor.

The `mathfont` package applies `fontspec`’s advances in font selection to math-mode typesetting, and this documentation explains `mathfont` as follows. Section 1 presents the basic functionality and related packages. Sections 2 and 3 explain how to use the default and local font-change commands, and users in a hurry will find the most important information here. Sections 4 and 5 discuss the Greek characters and mathematical symbols that `mathfont` provides, and section 6 describes the more complicated error messages that `mathfont` may throw. The remaining five sections detail the implementation. Section 7 lays out the initial implementation for the package, and sections 8 and 9 lay out the L<sup>A</sup>T<sub>E</sub>X code for default and local font changes, respectively. Section 10 covers the code for the unicode alphanumeric letterlike symbols, and the final section 11 contains the unicode hex values for every character supported by `mathfont`. Version history occurs on page p. 34. For an example of the package in action, see `mathfont_example.pdf`, which is included with the `mathfont` installation and is available on CTAN.

## 1 Basic Functionality

The `mathfont` package uses `fontspec` as a back end to load fonts for use in math mode, and it provides two ways to do this: (1) changing the default font for certain classes of math mode characters; and (2) defining new commands that change the font locally for the so-called “math alphabet” characters. (The math alphabet characters are all Latin letters, all Arabic numerals, and any Greek letters that `mathfont` has set the font for.) The package can change the default math font for Latin and Greek letters, Arabic numerals, and unicode alphanumeric symbols to any unicode OpenType or TrueType font. Tables 1 and 2 display the specific classes of characters that `mathfont`’s default font-change command acts on.

The package can be loaded with the standard `\usepackage` syntax, and it has three optional arguments: `packages`, `operators`, and `no-operators`. During loading, `mathfont` redefines two L<sup>A</sup>T<sub>E</sub>X internal macros to make symbol declaration compatible with unicode fonts, and the `packages` option determines when `mathfont` resets the two internal commands. If the user loads the package without the `packages` option, `mathfont` will reset the internal commands at the next `\usepackage` declaration, but with the argument, `mathfont` does not reset them at all. In practice, using this option should be harmless in most situations, and the issue is primarily one of convenience. The `\mathfont` command works only with these redefinitions, so once the package has reset the L<sup>A</sup>T<sub>E</sub>X kernel, it will not adjust the default font for any class of characters. Thus the `packages` option allows users to sprinkle `\mathfont` declarations throughout their preamble, and doing so may be advantageous depending on the situation. However, leaving the kernel modified could induce clashes with other packages, so proceed at your own risk! For users who provided the `packages` argument or are loading packages before the `\documentclass` declaration, the control sequence `\restoremathinternals` manually returns the internal commands to their default definition.

tions. It should be considered best practice to load `mathfont` without packages and put all `\mathfont` commands as soon after loading as possible.

The package arguments `operators` and `no-operators` determine `mathfont`'s behavior regarding the integral, summation, and product signs. The `operators` argument tells the package to adjust the font for these three symbols, and the `no-operators` argument does the opposite. As of version 1.4, the package executes the `no-operators` option by default, but users may want to enable this behavior depending on the desired math font and other symbols being used. See sections 2 and 5 for more information.

The package loads `fontspec` with the `no-math` option if and only if the user has not already loaded `fontspec`. Users who want `fontspec` without `no-math` or with other options in place can manually load it before requiring `mathfont`, and I strongly recommend that users who do so load `fontspec` with `no-math`. Alternatively, users who want to pass options to `fontspec` without loading it themselves can use L<sup>A</sup>T<sub>E</sub>X's `\PassOptionsToPackage` command before loading `mathfont`.

Compatibility with L<sup>A</sup>T<sub>E</sub>X comes at the expense of `mathspec`'s convenient space-adjustment character `"`, and spacing-conscious users can either manually add `\kern` or `\muskip` to their equations or redefine an active version of `"`.<sup>3</sup> For example, the code

```
\catcode`\\"=\active
\def"\#1{\ifmmode
    \kern<dimension>\relax #1\kern<other dimension>\relax
\else
    \char`\\"#1%
\fi}
```

will serve as a hack that very roughly approximates `mathspec`'s `"`. This code will redefine `"` to typeset a right double quotation mark in horizontal mode, but in math mode, the character will insert *dimension* and *other dimension* of white space on either side respectively of the following character. More advanced users can automate the dimensions by using T<sub>E</sub>X's `\if` conditional to test whether the following character needs a particular spacing adjustment. (For example, Computer Modern's math-mode *f* is notorious for being significantly wider than its italic counterpart.) Future versions of `mathfont` may provide an automated space-adjustment command, but it is not one of my priorities.

The functionality of `mathfont` is most closely related to that of the `mathspec` package by Andrew Gilbert Moschou.<sup>4</sup> These two packages incorporate the use of individual unicode characters into math mode, and their symbol declaration process is similar. Both use `fontspec` as a back end, and both create font-changing commands for math-mode characters. However, the functionality differs in three crucial respects: `mathfont` is compatible with L<sup>A</sup>T<sub>E</sub>X; it can adjust the font of basic mathematical symbols such as those in tables 5 and 6; and its local math-font-changing mechanisms provide a slightly greater level of flexibility than

---

<sup>3</sup>The problem isn't one of ability—L<sup>A</sup>T<sub>E</sub>X's programming capabilities tend to outweigh those of X<sub>H</sub>T<sub>E</sub>X. Rather, I'm unfamiliar with most of the workings of L<sup>A</sup>T<sub>E</sub>X. One of my eventual goals for this package is a Lua script that could automatically adjust spacing in math mode for any combination of two characters, but I don't know if or when I will be able to do that.

<sup>4</sup>Andrew Gilbert Moschou, “`mathspec`—Specify arbitrary fonts for mathematics in X<sub>H</sub>T<sub>E</sub>X,” <https://ctan.org/pkg/mathspec>.

what users can achieve with `mathspec`. Further, as far as I am aware, this package is the first to provide support for the unicode alphanumeric symbols listed in Table 2, even in the context of fonts without built-in math support. (Please let me know if this is incorrect!) In this way `mathfont`, like `mathspec`, is more versatile than the `unicode-math` package, although potentially less far-reaching.<sup>5</sup>

Users who want to stick with pdf<sup>L</sup>A<sub>T</sub>E<sub>X</sub> should consider Jean-François Burnol's `mathastext` as a useful alternative to `mathfont`.<sup>6</sup> This package allows the user to specify the math-mode font for a large subset of the ASCII characters and is the most closely related package to `mathfont` among those packages designed specifically for pdf<sup>L</sup>A<sub>T</sub>E<sub>X</sub>. Whereas `mathfont` works exclusively in the context of unicode fonts, `mathastext` was designed for the T1 and related encodings of Plain T<sub>E</sub>X and L<sup>A</sup>T<sub>E</sub>X, and `mathfont` provides support for a larger class of symbols. However, the `mathastext` functionality extends beyond that of `mathfont` in two notable aspects: (1) `mathastext` makes use of math versions, extra spacing, and italic corrections; and (2) `mathastext` allows users to change the font for the twenty-five non-alphanumeric characters supported by that package multiple times. After setting the default font for a class of characters, `mathfont` allows for that class only the local font changes outlined in section 3.

## 2 Setting the Default Font

The `\mathfont` command sets the default font for certain classes of characters. Its structure is given by

`\mathfont[<optional character classes>]{<font name>},`

where the *optional character classes* can be any set of keywords from Tables 1 and 2 separated by commas, and the *font name* can be any OpenType or TrueType font in a directory searchable by T<sub>E</sub>X. When specifying the *font name*, users need to input a name that `fontspec` will recognize and be able to load. Advanced users will note that `\mathfont` uses `\fontspec_set_family:Nnn` and therefore loads fonts in the same way as `\fontspec` and related macros from that package. Currently, `mathfont` does not support OpenType features in math mode. To change both math and text fonts simultaneously, the package provides the command

`\setfont{<font name>},`

which calls both `\mathfont` and `fontspec`'s `\setmainfont` using the *font name* as arguments. Most users will probably find this command sufficient for most applications. Both `\mathfont` and `\setfont` should appear only in the document preamble.

The user should specify any keyword optional arguments for `\mathfont` as entries in a comma-separated list. The order is irrelevant, and spaces between entries are permitted. For each item in the list, the package will change the math-mode font for that class of characters

<sup>5</sup>Will Robertson, “unicode-math—Unicode mathematics support for X<sub>E</sub>T<sub>E</sub>X and LuaT<sub>E</sub>X,” <https://ctan.org/pkg/unicode-math>.

<sup>6</sup>Jean-François Burnol, “mathastext—Use the text font in maths mode,” <https://ctan.org/pkg/mathastext>. In several previous versions of this documentation, I mistakenly stated that `mathastext` distorts T<sub>E</sub>X's internal mathematics spacing. In fact the opposite is true: `mathastext` preserves and in some cases extends rules for space between various math-mode characters.

Table 1: Math Alphabet Characters

Keyword	Meaning	Default shape
<code>upper</code>	Capital Latin letters	Italic
<code>lower</code>	Minuscule Latin letters	Italic
<code>greekupper</code>	Capital Greek letters	Upright
<code>greeklower</code>	Minuscule Greek letters	Italic
<code>digits</code>	Arabic numerals	Upright
<code>operator</code>	Operator font	Upright

to the mandatory argument. Leaving out the optional argument will cause the command to revert to its default behavior, and for most applications, that will be sufficient. If the user does not specify an optional argument for `\mathfont`, e.g. writes

```
\mathfont{Helvetica},
```

the package will change all math-mode Latin characters, Greek characters, digits, operators such as `log` or `sin`, and all symbols from Tables 5 and 6 to the font in the mandatory argument. (Specifically, all keywords from Table 1 and the `symbol` keyword from Table 2.) In this example, the new font would be Helvetica.

By default, `mathfont` will use either an upright or italic shape corresponding to each character-class keyword, but the user can override this setting by writing an equals sign next to the keyword and a shape suboption—either `roman` or `italic`—following that. Table 1 contains the default shapes for the keywords listed there, while the default shape for all classes of characters in Table 2 is upright. The package interprets the `roman` suboption as specifying an upright shape—normal shape in the language of the NFSS—and the `italic` suboption as specifying an italic shape. Currently `mathfont` does not support default font shapes beyond these two. For example, the command

```
\mathfont[upper=roman,lower=roman]{Times New Roman}
```

would change all math-mode Latin letters to Times New Roman with upright shape. As of version 1.4, `\mathfont` ignores all spaces in its optional argument, so the above code snippet is equivalent to

```
\mathfont[ upper = roman , lower = roman ]{Times New Roman}.
```

Technical point: `\mathfont` expands its optional argument inside an `\edef`, so the argument can contain any number of fully expandable control sequences. Users should also be aware that, in order to limit the number of symbol fonts in memory, `\mathfont` will not change the default font for a class of symbols once it has already done so.

The Unicode Consortium designates the Mathematical Alphanumeric Symbols (U+1D400–U+1D7FF) code block for several classes of letters and letterlike symbols that appear frequently in mathematical writing. The `mathfont` package provides easy access to these symbols through the `\mathfont` command, and Table 2 lists the corresponding keywords that should be used with `\mathfont` to do so. When the user calls `\mathfont` with any of the last five keywords from Table 2 in its optional argument, `mathfont` both declares the appropriate unicode characters as math symbols and defines the macro

`\math<keyword>{<argument>}.`

This control sequence takes one argument, and it converts the characters in its argument into the corresponding style. For example,

`\mathfont[bcal]{STIXGeneral}`

will set STIXGeneral as the font for bold caligraphic characters and define the command `\mathbcal` to access them in math mode. The argument of the macro produced this way must be a single string of Latin letters without braces or control sequences, although in somewhat idiosyncratic fashion, the `\mathbb` command can also accept Arabic numerals in its argument. Spaces and any character of catcode 12 will be ignored.

Because these commands can handle capital and minuscule Latin letters, the `mathfont` package significantly extends the functionality of `TEX`'s standard `\mathcal` command and the `\mathbb` command from the `amssymb` package. Users should note that typesetting symbols from a letterlike class of characters in Table 2 will require a unicode font that actually contains those characters, such as Symbola or STIXGeneral. That being said, users who need only a few alphanumeric symbols may be able to use a less specialized font that contains for example the characters from the Letterlike Symbols (U+2100–U+214F) code block. This block contains the blackboard bold versions of C, N, Q, R, and Z, and the fonts providing these characters are significantly more common than those that contain the full blackboard bold alphabet.

### 3 Local Font Changes

With `mathfont`, users can locally change the font in math mode by creating a new control sequence for each new font desired. The commands created this way function analogously to the standard math font macros from the `LATEX` kernel such as `\mathrm`, `\mathit`, and `\mathnormal`, and the package includes four basic commands to produce new control sequences. Table 3 lists these commands, and they all have the same argument structure: a control sequence as the first mandatory argument and a font name as the second. For example, the macro `\newmathrm` looks like

`\newmathrm{<control sequence>}{<font name>}.`

It defines the *control sequence* in its first argument to accept a string of characters that it then converts to the *font name* in the second argument with upright shape and medium

Table 2: Other Math Symbols

Keyword	Meaning
<code>symbols</code>	Basic mathematical symbols (includes punctuation)
<code>bb</code>	Blackboard Bold (double-struck)
<code>cal</code>	Caligraphic
<code>frak</code>	Fraktur
<code>bcal</code>	Bold Caligraphic
<code>bfrak</code>	Bold Fraktur

Table 3: Font-changing Commands

Command	Font Characteristics
<code>\newmathrm</code>	Upright shape; medium weight
<code>\newmathit</code>	Italic shape; medium weight
<code>\newmathbold</code>	Upright shape; bold weight
<code>\newmathboldit</code>	Italic shape; bold weight

weight. Writing

```
\newmathrm{\matharial}{Arial}
```

would create the macro

```
\matharial{<argument>},
```

which can be used only in math mode and which converts the math alphabet characters in its *argument* into the Arial font with upright shape and medium weight. The other three commands in Table 3 function in the same way except that they select different series or shape values for the font in question, and Table 3 lists this information.

Unlike the traditional `\mathrm` and company, `mathfont`'s local font change commands create macros that can act on Greek characters. If the user specifies the font for Greek letters using `\mathfont`, macros created with the commands from Table 3 will affect those characters; otherwise, they will not. Specifically, L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> defines Greek letters as `\mathord` characters, and `mathfont` changes this classification to `\mathalpha` type when it declares them as symbols. The local font change commands here act only on characters of class `\mathalpha`, so if the user doesn't set the font for `greekupper` or `greeklower` characters in a `\mathfont` command, any macro from this section will not be able to act on any Greek letters. Instead, they will still be typeset as `\mathord` characters in Computer Modern.

Together these four commands will provide users with the tools for almost all desired local font changes, but they inevitably will be insufficient for some particular case. Accordingly, `mathfont` provides the more general `\newmathfontcommand` macro that functions similarly to the commands from Table 3 but allows the user to specify certain font characteristics. Its argument structure is

```
\newmathfontcommand{<control sequence>}{<font name>}{<series>}{<shape>},
```

where the font name again means any OpenType or TrueType font in a directory searchable by T<sub>E</sub>X. The series and shape information refers to the NFSS codes for these attributes, and the control sequence in the first argument becomes the command that allows the user to access the specified font. Advanced users will note that these five macros are essentially wrapped versions of L<sup>A</sup>T<sub>E</sub>X's `\DeclareMathAlphabet`, and like `\mathfont`, they must be used in the document preamble.

## 4 Greek Characters

Unlike Plain T<sub>E</sub>X and L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub>, `mathfont` defines control sequences for all characters in the Greek alphabet. (T<sub>E</sub>X's OT encodings do not include the capital Greek characters that

Table 4: Greek Character Control Sequences

Modern Greek Characters		Ancient Greek Characters	
Capital	Minuscule	Capital	Minuscule
\Alpha*	\alpha	\Heta	\heta

\*Starred Modern Greek and all Ancient Greek letters are not provided by default and are defined only when the user calls `\mathfont` for `greekupper` and/or `greeklower` characters.

resemble Latin letters. Presumably Donald Knuth made this decision to conserve encoding slots.) All such control sequences instruct L<sup>A</sup>T<sub>E</sub>X to typeset the corresponding unicode Greek character, and `mathfont` also provides control sequences for several ancient Greek letters. This package's additional Greek character control sequences will become available once the user calls `\mathfont` for the corresponding class of Greek characters. Table 4 lists all such control sequences. I do not include typeset versions of these characters in this documentation because I wanted to avoid potential compilation problems regarding `mathfont.dtx`. However, see the

Table 5: Characters Corresponding to the `symbols` Keyword

Character	Control Sequence	Class	Punctuation	Class
#	\#	\mathord	.	\mathord
\$	\\$	\mathord	@	\mathord
%	\%	\mathord		\mathord
&	\&	\mathord	,	\mathord
\P	\P	\mathord	"	\mathord
\S	\S	\mathord	+	\mathbin
\L	\pounds	\mathord	-	\mathbin
\neg	\neg	\mathord	*	\mathbin
\infty	\infty	\mathord	/	\mathbin
\partial	\partial	\mathord	=	\mathrel
\sum*	\sum	\mathop	<	\mathrel
\prod*	\prod	\mathop	>	\mathrel
\int*	\int	\mathop	:	\mathrel
\times	\times	\mathbin	(	\mathopen
\div	\div	\mathbin	)	\mathclose
\pm	\pm	\mathbin	[	\mathopen
\cdot	\cdot	\mathbin	]	\mathclose
\bullet	\bullet	\mathbin	!	\mathclose
\dag	\dag	\mathbin	?	\mathclose
\ddag	\ddag	\mathbin	,	\mathpunct
\setminus	\setminus	\mathbin	;	\mathpunct
\leq	\leq	\mathrel		
\geq	\geq	\mathrel		
\sim	\sim	\mathrel		
\approx	\approx	\mathrel		
\equiv	\equiv	\mathrel		
\mid	\mid	\mathrel		
\parallel	\parallel	\mathrel		
:	\colon	\mathpunct		
\dots	\dots	\mathinner		

\*If the package option `operators` is enabled.

file `mathfont_greek.pdf`, which is included with the `mathfont` installation and is available on CTAN. As with the unicode letterlike symbols, not all fonts contain ancient Greek or even modern Greek characters, and setting `greekupper` and `greeklower` to a font without these symbols will produce a document with missing characters.

Table 6: Extra Macros Created with the `symbols` Keyword

Character	Control Sequence	Class	Character	Control Sequence	Class
\	<code>\mathbackslash</code>	<code>\mathord</code>	{	<code>\leftbrace</code>	<code>\mathopen</code>
°	<code>\degree</code>	<code>\mathord</code>	}	<code>\rightbrace</code>	<code>\mathclose</code>
Δ*	<code>\increment</code>	<code>\mathord</code>			
,	<code>\comma</code>	<code>\mathord</code>			

\*As of version 1.5, `\Delta` typesets the Greek letter and `\increment` typesets the increment symbol. The difference will become significant in several situations: (1) when a font contains only one of the symbols or contains two glyphs that appear different; (2) when using local font change commands, which can act on `\Delta` but not `\increment`; or (3) when the user wants to change the font for only one of the Greek letter or increment character. Note that most major unicode fonts contain separate Delta and increment symbols.

## 5 Math Symbols

With the `symbols` keyword, the `\mathfont` command will change the default math-mode font for all characters in Table 5. For the control sequences on the left half of the table that function in both math and horizontal modes, `mathfont` acts on the character only when it appears in math mode, so the character will be unaffected when used in regular text. The same is true for the punctuation marks on the right side. By default the package does not act on the integral, summation, and product symbols. As stated previously, users can enable or disable this behavior with the optional package arguments `operators` and `no-operators` respectively, and doing so may be desirable depending on which math symbols the user wants and the math font in use. Finally, a technical point: when `mathfont` acts on the `symbols` characters, it redefines the four macros `\#`, `\$`, `\%`, and `\&` as robust commands more complicated than a single `\char`, so constructs like `\number\#` will need to be rewritten as `\number`\'#`.

Choosing which unicode characters to recode is something of a delicate task because so few unicode fonts contain more than the most basic mathematics symbols. In designing this portion of `mathfont`, I attempted to find the largest set of characters that reliably appears in every or nearly every major unicode font, and that's why Table 5 contains no arrows, subset and element symbols, quantifiers, and complicated operation and grouping symbols. Most standard unicode fonts don't contain those glyphs, and I wanted `mathfont` to be useful for as many fonts as possible. That being said, the package provides the five new control sequences listed in Table 6. The `\degree` command functions as the unicode alternative to the `$^{\circ}` construction, and the other four control sequences print the associated unicode character. None of these characters are coded as delimiters, so they will not respond to L<sup>A</sup>T<sub>E</sub>X's `\left` and `\right` sizing commands.<sup>7</sup> The package also provides an additional comma character to typeset large integers. T<sub>E</sub>X users have likely noticed the extra space after commas in math mode, e.g. 10,000 versus 10,000, and `mathfont`'s `\comma` solves this problem. Here the first ten thousand uses a standard `,` while the second uses `\comma`. In

---

<sup>7</sup>Because of time constraints, I couldn't figure out how to use L<sup>A</sup>T<sub>E</sub>X's `\Udelim` primitive to code the backslash and braces properly. Any suggestions in this area are welcome.

other words, the control sequence typesets a comma in math mode but does not insert the extra space following it. I recommend using `\comma` basically only for large integers, but I leave the ultimate decision to the user.

## 6 Handling Errors

Most of `mathfont`'s error messages are self-explanatory, and the help text will contain instructions for how to resolve the message. Nevertheless, some of the possible error messages warrant additional explanation.

The most salient error is the “Missing X<sub>E</sub>T<sub>E</sub>X or LuaT<sub>E</sub>X” message. If a user tries to load `mathfont` without one of these two engines, T<sub>E</sub>X will crash, either through `mathfont`'s fatal error message or when `fontspec` performs its own engine checks. Advanced users should note that `mathfont` doesn't actually determine the typesetting engine. Rather, it checks whether the X<sub>E</sub>T<sub>E</sub>X and LuaT<sub>E</sub>X primitives `\Umathcode` and `\Umathchardef` are defined, so if for some reason these control sequences have definitions when the user loads `mathfont`, `fontspec`'s more robust engine checks will cause T<sub>E</sub>X to abort. The reasoning here is straightforward: `mathfont` verifies only that the current typesetting engine provides the commands that it directly needs, so its potential functionality remains as broad as possible. If `fontspec` becomes compatible with a third engine that also provides (analogues of) `\Umathcode` and `\Umathchardef`, there is no reason to prevent `mathfont` from working with that engine as well. The obvious corollary to this setup is that users with very old X<sub>E</sub>T<sub>E</sub>X or LuaT<sub>E</sub>X distributions may see this fatal error even when running one of these engines, and the solution is probably to upgrade to a more recent version of the engine in question. Unfortunately, I do not know when X<sub>E</sub>T<sub>E</sub>X and LuaT<sub>E</sub>X introduced these primitives.<sup>8</sup>

The `fontspec` package includes a “no-math” option, and `mathfont` expects `fontspec` to be loaded with this option. As mentioned previously, `mathfont` loads `fontspec` by default, but users can load `fontspec` before `mathfont` if they want to manually specify the package options. Alternatively, L<sub>A</sub>T<sub>E</sub>X's `\PassOptionsToPackage` may be an even better way to proceed. If `mathfont` detects that `fontspec` was loaded without the `no-math` option, it will issue an error message saying so. This error is not paramount in the sense that the document will compile almost normally if a user ignores it, but `mathfont` will probably have trouble changing the font of certain math-mode characters in this situation. During development, Arabic numerals posed a particular challenge in this regard.

The “internal commands restored” error arises when the user calls `\mathfont` in a situation where the package already restored the small portion of the L<sub>A</sub>T<sub>E</sub>X kernel that it adjusts when loaded. Unless the user loads `mathfont` with the `packages` option, this process happens when the user next calls `\usepackage`, and `mathfont` will not carry out any calls to `\mathfont` at that point. As mentioned previously, users who want to manually restore the L<sub>A</sub>T<sub>E</sub>X kernel can do so with the `\restoremathinternals` command. It is also worth pointing out if the user tries to reset the default font for some characters with `\mathfont`, the package will issue a warning but will not halt the compilation process.

---

<sup>8</sup>However, the manual for a beta version of LuaT<sub>E</sub>X, v. 0.70.1, includes both primitives, so they are at least as old as May 2011. See  
<https://osl.ugr.es/CTAN/obsolete/systems/luatex/base/manual/luatexref-t.pdf>

What should you do if you can't resolve an error? First, always, always make sure that you spelled all of your commands correctly and closed all braces and brackets. Then check the `mathfont` documentation—you may be trying to do something outside the scope of the package, or you may be dealing with a special case. In particular, read all the sections of the documentation that relate to the command or commands you are having trouble with. The internet is a great resource, and websites such as the TeX StackExchange, ShareLaTeX, and Wikibooks's LaTeX wiki are often invaluable in dealing with TeX-related issues. Definitely ask another human as well! At that point you should email the author about your code—you might have identified a bug. I welcome emails about `mathfont` and will make every effort to write back to correspondence about the package, but I cannot guarantee a timely response.

## 7 Implementation

First and foremost, the package needs to declare itself. The `packages` option changes the `\if@packages` boolean from false to true. Ditto for `operators`.

```

1 \NeedsTeXFormat{LaTeX2e}
2 \ProvidesPackage{mathfont}[2019/04/07 v. 1.5 Package mathfont]
3 \newif\if@packages
4 \newif\if@operators
5 \DeclareOption{packages}{\@packagestrue}
6 \DeclareOption{operators}{\@operatorstrue}
7 \DeclareOption{no-operators}{\@operatorsfalse}
8 \DeclareOption*{\PackageError{mathfont}
9   {Option "\CurrentOption" unknown}
10  {I'm ignoring that option because\MessageBreak
11    I don't know what it means.}}
12 \ProcessOptions*
```

Some error and informational messages.

```

13 \def\M@FontChangeInfo#1{\PackageInfo{mathfont}
14   {Changing math-mode #1\MessageBreak
15    characters to \csname M@font\the\@count\endcsname\MessageBreak

129 \fi
130 \M@XeTeXLuaTeXError
131 \endgroup

```

We load the `fontspec` package in order to use its main font loading mechanism, and we `\let` the macro `\@newfont` take on this function. We also make sure that `fontspec` was loaded with the `no-math` option because without it, `fontspec` may cause trouble with some of the math characters. If `\g__fontspec_math_bool` is equal to 1, `mathfont` will issue an error message.

```

132 \@ifpackageloaded{fontspec}
133   {\ifnum\csname g__fontspec_math_bool\endcsname=1
134     \M@NoMathError
135   \fi}{\RequirePackage[no-math]{fontspec}}
136 \expandafter\let\expandafter\@newfont
137   \csname fontspec_set_family:Nnn\endcsname

```

We save `\set@mathchar` and `\set@mathsymbol` from the L<sup>A</sup>T<sub>E</sub>X kernel so we can change their definitions. We need to adapt these macros for use with unicode fonts, and we replace `\mathcode` and `\mathchardef` respectively with the X<sub>E</sub>T<sub>E</sub>X and LuaT<sub>E</sub>X primitives `\Umathcode` and `\Umathchardef`. The unicode primitives support decimal input using a + sign, and we take advantage of that feature to avoid hexadecimal conversions.

```

138 \M@SetInternalsInfo
139 \let\@set@mathchar\set@mathchar
140 \let\@set@mathsymbol\set@mathsymbol
141 \def\set@mathchar#1#2#3#4{%
142   \multiply\count\z@ by 16\relax
143   \advance\count\z@\count\tw@
144   \global\Umathcode`#2=\mathchar@type#3+#1+\count\z@}
145 \def\set@mathsymbol#1#2#3#4{%
146   \multiply\count\z@ by 16\relax
147   \advance\count\z@\count\tw@
148   \global\Umathchardef#2\mathchar@type#3+#1+\count\z@}

```

We need to keep track of the number of times we have loaded a font, and the count `\M@count` fulfills this role. We will use the `\M@toks` object to record a message that displays when the user calls `\mathfont`.

```

149 \newcount\M@count
150 \M@count\z@
151 \newtoks\M@toks

```

We create necessary booleans and the default math font shapes.

176 \def\@bcalshape{roman}
177 \def\@bfrakshape{roman}

```

The command `\check@option@valid` confirms that a user's keyword option is legitimate. The macro defines `\@temperror` to be an invalid option error and loops through all possible options. If the command argument matches one of the correct possibilities, the package changes `\@temperror` to `\relax`. The macro ends this process with a call to `\@temperror`, so the package issues an error if and only if the specified option is invalid. We have to initialize the blackboard, calligraphic, and fraktur commands separately because they don't use the same encoding-alphabet system as the regular letters and digits. The `\define@<keyword>` macro does this.

```

178 \def\check@option@valid#1{%
179   \def\@temperror{\M@InvalidOptionError{#1}}
180   \@for\@j:=upper,lower,greekupper,greeklower,digits,symbols,operator\do{%
181     \ifx\@j#1
182       \let\@temperror\relax
183     \fi}
184   \@for\@j:=bb,cal,frak,bcal,bfrak\do{%
185     \ifx\@j#1
186       \let\@temperror\relax
187     \csname define@\@j\endcsname
188   \fi}

```

```

189  \@temperror}

Do the same thing for the suboption.

190 \def\check@suboption@valid#1{%
191   \def\@temperror{\M@InvalidOptionError{#1}}
192   \@for\@j:=roman,italic\do{%
193     \ifx\@j#1
194       \let\@temperror\relax
195     \fi}
196  \@temperror}

```

We want to allow the user to specify options using an `xkeyval`-type syntax. However, we do not need the full package; a slim 24 lines of code will suffice. We use the next three macros to parse the optional argument of `\mathfont`. The control sequence

```
\@gobblesp <text>\@nil<macro>
```

takes the first string of consecutive non-space tokens in *text* and sets it to be the contents of *macro*. We remove initial spaces with `\@ifnextchar` and use delimiters in the definition of `\g@bblesp@def` for the token selection and final storage.

```

197 \def\@gobble@equals#1=#2\@nil{#1}
198 \def\@gobblesp{\@ifnextchar\empty\relax\g@bblesp@def}
199 \def\g@bblesp@def#1 #2\@nil#3{\def#3{#1}}

```

Parse the option and suboption. When `\mathfont` expands, it loops through its optional argument with `\@for`, and for each option-suboption token string, it calls `\parse@suboption` on the token string followed by `=\@nil`. Doing so splits the option and suboption, and `\parse@suboption` handles each separately. All tokens before the first `=` become the option, and all tokens after become the suboption. The macro removes any extra spaces with `\@gobblesp` and puts the option in `\@tempa`. We include the extra `\\"` in the argument of `\@gobblesp` because we need to check that the option portion of the token string contains non-space characters. If not, `\@tempa` will become `\\"`, and the package issues an error. (If yes, `\g@bblesp@def` will gobble the `\\"` and following space, so it won't matter.)

```

200 \def\parse@suboption#1=#2\@nil{%
201   \@gobblesp#1 \\ \@nil\@tempa
202   \def\@tempb{\\"}
203   \ifx\@tempa\@tempb
204     \M@MissingOptionError
205   \else
206     \check@option@valid\@tempa
207   \fi

```

Adding the `=\@nil` to the token string allows us to see immediately whether the user specified a suboption by checking if `#2` is empty. If not, the macro again removes extra spaces with `\@gobblesp`, and we check whether `\@let@token` from the `\@ifnextchar` is the extra `=`. That would mean the user typed `=` but didn't follow it with a suboption, and in that case, `mathfont` issues an error. If the suboption is valid, the macro gobbles the last `=` with `\@gobble@equals` and stores the result in `\@tempb`.

```

208   \def\@tempb{#2}
209   \ifx\@tempb\@empty

```

```

210      \@suboptionpresentfalse
211  \else
212      \@gobblesp#2 \@nil\@tempb
213  \if\@let@token=
214      \M@MissingSuboptionError
215  \else
216      \edef\@tempb{\expandafter\@gobble@equals\@tempb=\@nil}
217      \check@suboption@valid\@tempb
218  \fi
219  \@suboptionpresenttrue
220 \fi}

```

## 8 Implementation of Default Font Changes

The user-level command `\mathfont` passes its mandatory argument to `\newfont` through the `\mathfont` command. If the user includes `\mathfont` with an optional argument, `\mathfont` will loop through each item in the optional argument using `\for` and set the math font for each of those classes of characters. If the user does not specify an optional argument, `\mathfont` calls `\mathfont` with the list of entries from Table 1 in brackets. The `\mathfont` macro proceeds in several steps. First, it checks if `\set@mathchar` has been reset, and if so, the current call to `\mathfont` will do nothing. If not, the macro loads the user's font with `\newfont` and checks its keyword optional arguments. The command declares the appropriate symbol fonts if necessary, actually sets the math font by calling `\M@<keyword>@set` command, and records that the font change occurred by switching the appropriate boolean to true. Finally, `\mathfont` increments `\M@count` by one.

The package stores each new font in a macro of the form `\M@font<number>`, where *number* is given by the current value of `\M@count`. The name of the corresponding symbol fonts is `M<shape><number>`, where *shape* is either `roman` or `italic` and *number* is again the value of `\M@count`. For each keyword from Tables 1 and 2, the package originally defines `\<keyword>shape` as the default shape for that collection of characters. If the user specifies a suboption for any keyword in the optional argument of `\mathfont`, the package overrides the default shape by redefining `\<keyword>shape` to the value of the suboption. For example, suppose the user loads `mathfont` and then immediately writes

```
\mathfont [upper=roman]{Helvetica}.
```

In this situation, `mathfont` would define `\M@font0` to be the internal name of Helvetica, and the corresponding symbol font names would be `Mroman0` and `Mitalic0`. Because the user specified a suboption, `\mathfont` would redefine `\M@uppershape` to the token string “`roman`,” and the package will use `\M@uppershape` later to specify the symbol font for capital Latin characters.

```

221 \def\mathfont{\ifnextchar[{\mathfont
222   {\mathfont [upper,lower,greekupper,greeklower,digits,symbols,operator]}}
223 \def\mathfont[#1]#2{%
224   \ifx\@set@mathchar\set@mathchar
225     \M@InternalsRestoredError

```

```

226 \else
227   \M@toks{}
228   \mathfont@firstoptiontrue
229   \expandafter\newfont\csname M@font\the\M@count\endcsname{}\#2}
230   \edef@\tempa{\#1}
231   \for@\i:=\tempa\do{\expandafter\parse@suboption@\i=\@nil

```

If the user calls `\mathfont` and tries to reset the font for a certain class of characters, `mathfont` will issue a warning, and the package will not adjust the font for those characters. Notice the particularly awkward syntax with the `\csname`-`\endcsname` pairs. Without this construct, `TeX` wouldn't realize that `\csname if@\tempa\endcsname` matches the eventual `\fi`, and the `\for` loop would break. (`TeX` does not have a smart if-parser!)

```

232   \expandafter\ifx\csname if@\tempa\expandafter\endcsname
233     \csname iftrue\endcsname
234     \M@CharsSetWarning{\tempa}
235   \else
236     \if@mathfont@firstoption
237       \mathfont@firstoptionfalse
238     \else
239       \expandafter\M@toks\expandafter{\the\M@toks, }
240     \fi
241     \edef@\tempc{\the\M@toks\tempa}
242     \expandafter\M@toks\expandafter{\tempc}

```

Handle the case with a suboption.

```

243   \if@suboptionpresent
244     \expandafter\edef\csname @\tempa shape\endcsname{@\tempb}
245     \edef@\tempc{\the\M@toks\space(@\tempb)}
246     \expandafter\M@toks\expandafter{\tempc}
247   \fi

```

For both possible shapes, check whether the package has already declared that version of the current font for use in math mode using `\@ifundefined`. If not, do so.

```

248   \def@\tempb{roman}
249   \expandafter\ifx\csname @\tempa shape\endcsname@\tempb
250     \@ifundefined{symMroman\the\M@count}%
251       \DeclareSymbolFont{Mroman\the\M@count}{TU}%
252         {\csname M@font\the\M@count\endcsname}{m}{n}{}}
253   \fi
254   \def@\tempb{italic}
255   \expandafter\ifx\csname @\tempa shape\endcsname@\tempb
256     \@ifundefined{symMitalic\the\M@count}%
257       \DeclareSymbolFont{Mitalic\the\M@count}{TU}%
258         {\csname M@font\the\M@count\endcsname}{m}{it}{}}
259   \fi

```

And now the magic happens.

```

260   \M@FontChangeInfo{\tempa}
261   \csname M@\tempa \set\endcsname

```

```

262      \csname @\@tempa true\endcsname
263      \fi}
264      \advance\M@count\@ne\relax
265      \message{:: mathfont :: following keyword(s) changed to #2:^^J%
266      --\the\M@toks.^^J}
267      \fi}
268 \onlypreamble\mathfont

```

We end the section by coding `\setfont`.

```

269 \def\setfont#1{\mathfont{#1}\setmainfont[Ligatures=TeX]{#1}}
270 \onlypreamble\setfont

```

## 9 Implementation of Local Font Changes

The general `\newmathfontcommand` macro creates commands that locally change the math font. This macro creates a new math alphabet, and it stores that alphabet in the user-provided control sequence. First, we check to make sure that the user provided a control sequence for the first argument of `\newmathfontcommand`, and if the user did not, `\check@csarg` issues an error.

```

271 \def\check@csarg#1#2#3{%
272   \ifcat\relax\noexpand#2
273     \def\@tempa{#2}
274     \@newfont\@tempb{}{#3}
275     \expandafter\newmathfontcommand
276   \else
277     \M@MissingControlSequenceError#1
278   \fi}

```

Now declare the math alphabet.

```

279 \def\@newmathfontcommand#1#2{\expandafter
280   \DeclareMathAlphabet\expandafter{@tempa}{TU}{@tempb}{#1}{#2}}
281 \def\newmathfontcommand{\check@csarg\newmathfontcommand}
282 \onlypreamble\newmathfontcommand

```

Then provide the four default versions.

```

283 \def\newmathrm#1#2{\check@csarg\newmathrm{#1}{#2}{m}{n}}
284 \def\newmathit#1#2{\check@csarg\newmathit{#1}{#2}{m}{it}}
285 \def\newmathbold#1#2{\check@csarg\newmathbold{#1}{#2}{b}{n}}
286 \def\newmathboldit#1#2{\check@csarg\newmathboldit{#1}{#2}{b}{it}}
287 \onlypreamble\newmathrm
288 \onlypreamble\newmathit
289 \onlypreamble\newmathbold
290 \onlypreamble\newmathboldit

```

## 10 Implementation of Alphanumeric Symbols

Each `\define@⟨keyword⟩` macro redefines one of the standard `\math⟨keyword⟩` commands. The new versions first check if they are in math mode using `\check@mmode` and then scan all tokens of their argument using `\ctfor`. For each token, the macro calls `\M@⟨keyword⟩@⟨token⟩`, which evaluates to a `\mathord` symbol in the desired style.

```
291 \def\check@mmode#1#2{%
292   \let\@tempa#2%
293   \ifmmode
294     \expandafter\@tempa
295   \else
296     \M@HModeError#1%
297     \leavevmode\expandafter$\expandafter\@tempa
298   \fi}
299 \def\process@tokens#1#2{\@tfor\@k:=#1\do{\csname M@#2@\@k\endcsname}}
300 \def\define@bb{%
301   \M@CommandInitializeInfo{blackboard bold}
302   \def\mathbb{\check@mmode\mathbb\@mathbb}
303   \def@\mathbb##1{\process@tokens{##1}{bb}}}
304 \def\define@cal{%
305   \M@CommandInitializeInfo{calligraphic}
306   \def\mathcal{\check@mmode\mathcal\@mathcal}
307   \def@\mathcal##1{\process@tokens{##1}{cal}}}
308 \def\define@frak{%
309   \M@CommandInitializeInfo{fraktur}
310   \def\mathfrak{\check@mmode\mathfrak\@mathfrak}
311   \def@\mathfrak##1{\process@tokens{##1}{frak}}}
312 \def\define@bcal{%

Finally a bit of housekeeping. We redefine `\#`, `\$`, `\%`, and `\&` as robust commands that expand to previously declared `\mathhash`, etc. commands in math mode and retain their standard `\char` definitions otherwise. Other commands that function in both math and horizontal modes such as `\S` or `\dag` also use this technique. The last three commands defined here preserve the Computer Modern font for characters used in several math-mode symbols.

```

# Version History

**1.1b** ..... July 2018  
–initial release

**1.2** ..... August 2018  
–minor bug fix for `\mathfrak`  
–eliminated redundant batchfile

**1.3** ..... January 2019  
–added `symbols` keyword  
–created `mathfont_example.pdf`  
–corrected the description of the  
`mathastext` package  
–font-change `\message` added to  
`\mathfont`

**1.4** ..... April 2019  
–`\setfont` command added  
–`\mathfont` optional argument can parse  
spaces  
–`no-operators` now default package  
optional argument  
–added `\comma` command  
–new fancy fatal error message  
–improved messaging for `\mathfont`  
–internal command `\mathpound` changed  
to `\mathhash`  
–added a missing #1 after `\char`\"` in the  
example code on p. 3

**1.5** ..... April 2019  
–separated `\increment` and `\Delta`  
–version history added  
–initial “off-the-shelf” use insert added

# Index

Numbers written in italic refer to the page where the corresponding entry is described; numbers underlined refer to the code line of the definition; numbers in roman refer to the code lines where the entry is used.
