10 Package <code>xintexpr</code> implementation	291

This is 1.2q of 2018/02/06.

- Release 1.2q of 2018/02/06 had some breaking changes:

- new output for the `\xintBezout` macro (`xintgcd`),
- the `xintexpr` operators `/:` (aka '`mod`') and `//`, and the supporting macros from `xintcore` and `xintfrac`, are now associated with the *floored* division. Formerly it was the *truncated* division. This is breaking change for operands of opposite signs.

Improvements and new features:

- `xinttools` macro `\xintListWithSep` is faster (first update since 1.04-2013/04/25...).
- `divmod()` function added to the `xintexpr` parsers,
- `\xintdefvar`, `\xintdeffloatvar`, `\xintdefiivar` extended to allow multiple simultaneous assignments.

- Release 1.2o of 2017/08/29 deprecated those macros from `xintcore` and `xint` which filtered their arguments via `\xintNum`. Currently these macros execute as formerly but raise an error message. This deprecation is overruled for most if `xintfrac` is loaded as it provides their proper definitions. Some however (like `\xintiAdd`) remain deprecated even if loading `xintfrac`. All these deprecated macros are destined to be removed at some future release.

A few macros got renamed (e.g. `\xintNot` became `\xintNOT`.) Former names emit a deprecation error and will get removed at some future release.

- Release 1.2n of 2017/08/06 removed the `xintbinhex` dependencies upon `xintcore`; the package now depends upon, and loads, only `xintkernel`. The allowed maximal size for the inputs of the base conversion macros got increased. The speed got slightly improved.

- Release 1.2m of 2017/07/31 rewrote entirely the `xintbinhex` module in the style of the techniques from 1.2 `xintcore`. The new macros expand faster but their inputs are now limited to a few thousand characters (the earlier routines, which dated back to 1.08 could handle (slowly) tens of thousands of digits.)
- Release 1.2l of 2017/07/26 refactored the subtraction and also `\xintiiCmp` got a rewrite. It should certainly use `\pdfstrcmp` for dramatic speed-up but I do not want to have to worry about multi-engine usage.

Some utility routines in `xintcore` manipulating blocks of eight digits and still in $O(N^2)$ style got rewritten analogously to the 1.2i version of macros such as `\xintInc`. Also `\xintiNu`m was revisited.

The arithmetic macros of `xintcore` and all macros of `xintfrac` using `\XINT_infrac` were made compatible with arguments using non-delimited `\the\numexpr` or `\the\mathcode` etc... But `\xintiiAbs` and `\xintiiOpp` were not modified (to avoid some overhead) as well as routines such as `\xintInc` which are primarily for internal usage.

- Release 1.2i of 2016/12/13 rewrote some legacy macros like `\xintDSR` or `\xintDecSplit` in the style of the techniques of 1.2. But this means also that they got limited to about 22480 digits for the former and 19970 digits for the latter (this is with the input stack size at 5000 and the maximal expansion depth at 10000.) This is not really an issue from the point of view of calling macros (such as `\xintTrunc`, `\xintRound`), because they usually had since 1.2 their own limitation at about 19950 digits from other code parts (such as division.) The macro `\xintXTrunc` (which is not f-expandable however) can produce tens of thousands of digits and it escapes these limitations. Old macros such as `\xintLength` are not limited either (incidentally it got a lifting in 1.2i.) The macros from `xinttools` (`\xintKeep`, `\xintTrim`, `\xintNthElt`) also are not limited (but slower.)
- Release 1.2 of 2015/10/10 entirely rewrote the core arithmetic routines located in `xintcore`. The parser of `xintexpr` got faster and the limitation at 5000 digits per number was removed.
- Extensive changes in release 1.1 of 2014/10/28 were located in `xintexpr`. Also with that release, packages `xintkernel` and `xintcore` were extracted from `xinttools` and `xint`, and `\xintAdd` was modified to not multiply denominators blindly.

Some parts of the code still date back to the initial release, and at that time I was learning my trade in expandable TeX macro programming. At some point in the future, I will have to re-examine the older parts of the code.

Warning: pay attention when looking at the code to the catcode configuration as found in `\XINT_setcatcodes`. Additional temporary configuration is used at some locations. For example ! is of catcode letter in `xintexpr` and there are locations with funny catcodes e.g. using some letters with the math shift catcode.

This package provides the common minimal code base for loading management and catcode control and also a few programming utilities. With 1.2 a few more helper macros and all *\chardef*'s have been moved here. The package is loaded by both *xintcore.sty* and *xinttools.sty* hence by all other packages.

First appeared as a separate package with release 1.1.

1.2i adds *\xintreplicate*, *\xintgobble*, *\xintLengthUpTo* and *\xintLastItem*, and improves the efficiency of *\xintLength*.

1.1 Catcodes, ε-T_EX and reload detection

The code for reload detection was initially copied from HEIKO OBERDIEK's packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

1.2 Package identification

Inspired from HEIKO OBERDIEK's packages. Modified in 1.09b to allow re-use in the other modules. Also I assume now that if `\ProvidesPackage` exists it then does define `\ver@<pkgname>.sty`, code of HO for some reason escaping me (compatibility with LaTeX 2.09 or other things ??) seems to set extra precautions.

1.09c uses e-_TE_X `\ifdefined`.

```

123 \ifdefined\ProvidesPackage
124   \let\XINT_providespackage\relax

```

1.9 *\xint_zapspaces*

1.1. This little utility zaps leading, intermediate, trailing, spaces in completely expanding context (`\edef`, `\csname ... \endcsname`).

```
\xint_zapspaces foo<space>\xint_gobble_i
```

Will remove some brace pairs (but not spaces inside them). By the way the `\zap@spaces` of LaTeX2e handles unexpectedly things such as `\zap@spaces 1 {22} 3 4 \@empty` (spaces are not all removed). This does not happen with `\xint_zapspaces`.

Explanation: if there are leading spaces, then the first #1 will be empty, and the first #2 being undelimited will be stripped from all the remaining leading spaces, if there was more than one to start with. Of course brace-stripping may occur. And this iterates: each time a #2 is removed, either we then have spaces and next #1 will be empty, or we have no spaces and #1 will end at the first space. Ultimately #2 will be `\xint_gobble_i`.

This is not really robust as it may switch the expansion order of macros, and the `\xint_zapspaces` token might end up being fetched up by a macro. But it is enough for our purposes, for example:

```
\the\numexpr \xint_zapspaces 1 2 \xint_gobble_i\relax  
expands to 12, and not 12\relax.
```

1.2e adds `\xint_zapspaces_o`. Expansion of #1 should not gobble a space!
Made long with 1.2i.

```
223 \long\def\xint_zapspaces #1 #2{#1#2\xint_zapspaces }% 1.1
224 \long\def\xint_zapspaces_o #1{\expandafter\xint_zapspaces#1 \xint_gobble_i}%
```

1.10 *\odef*, *\oodef*, *\fdef*

May be prefixed with `\global`. No parameter text.

```

233 \ifdefined\fdef\else\let\fdef\xintfdef\fi
```

1.11 *\xintReverseOrder*

`\xintReverseOrder`: does NOT expand its argument.

Attention: removes brace pairs.

For digit tokens only a faster reverse macro is provided as `\xintReverseDigits` from 1.2 `xint-core.sty`.

For comma separated items, 1.2g has (not user documented) `\xintCSVReverse` in `xinttools.sty`.

```

1.12 `\xintLength`

`\xintLength` does NOT expand its argument. See `\xintNthElt{0}` from `xinttools.sty` which f-expands its argument.

1.2g has (not user documented) `\xintCSVLength` in `xinttools.sty`.

1.2i has rewritten this venerable macro. New code is about 40% faster across all lengths. Was again slightly changed for 1.2j (cosmetic).

```

1.14 *\xintLengthUpTo*

1.2i for use by *\xintKeep* and *\xintTrim*.

\xintLengthUpTo{N}{List} produces -0 if *length(List)>N*, else it returns N-*length(List)*. Hence subtracting it from N always computes *min(N,length(List))*.

Does not expand its second argument (it is used by *\xintKeep* and *\xintTrim* with already expanded argument). Not a user macro. 1.2j rewrote the ending and changed the loop interface. The argument N **must be non-negative**.

1.15 \xintreplicate

Added with 1.2i. This is cloned from `\prg_replicate:nn` from expl3, see Joseph's post at
<http://tex.stackexchange.com/questions/16189/repeat-command-n-times>

I posted there an alternative not using the chained `\csname`'s but it is a bit less efficient (except perhaps for thousands of repetitions). The code in Joseph's post does `|#1|` replications when input `#1` is negative and then activates an error triggering macro; here we simply do nothing when `#1` is negative.

When `#1` is already explicit digits (even `#1=0`, but non-negative) one can call the macro directly as `\romannumeral\XINT_rep #1\endcsname {foo}` to skip the `\numexpr`.

Expansion must be triggered by a `\romannumeral`.

```

1.16 *\xintgobble*

Added with 1.2i. I hesitated about allowing as many as $9^{6-1}=531440$ tokens to gobble, but $9^{5-1}=59058$ is too low for playing with long decimal expansions.

Like for *\xintreplicate*, a *\romannumeral* is needed to trigger expansion.

I wrote in a similar spirit an *\xintcount*. But it proved slower than the upgraded 1.2i *\xintLength* in all the range up to thousands of tokens.

```

1.17 `\xintMessage`, `\ifxintverbose`

1.2c added it for use by `\xintdefvar` and `\xintdeffunc` of `xintexpr`. 1.2e uses `\write128` rather than `\write16` for compatibility with future extended range of output streams, in LuaTeX in particular.

```

483 \def\xintMessage #1#2#3{%
484     \immediate\write128{Package #1 #2: (on line \the\inputlineno)}%
485     \immediate\write128{\space\space\space\space#3}%
486 }%
487 \newif\ifxintverbose

```

1.18 (WIP) Expandable error message

Incorporated in 1.21 release, but really belongs to next major release.

This is copied over from l3kernel code. I am using `\ ! /` control sequence though, which must be left undefined. `\xintError:` would be 6 letters more already. Utiliser `\FPE:` ? (mais ce n'est pas uniquement du « floating point »)

Always used in context where expansion was launched by a `\romannumeral0` or `\romannumeral`^@`.

```

Release 1.09g of 2013/11/22 splits off `xinttools.sty` from `xint.sty`. Starting with 1.1, `xint-tools` ceases being loaded automatically by `xint`.

2.1 Catcodes, ε - \TeX and reload detection

The code for reload detection was initially copied from HEIKO OBERDIEK's packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

```

1 \begingroup\catcode61\catcode48\catcode32=10\relax%
2   \catcode13=5    % ^^M
3   \endlinechar=13 %

2.4 \xintRevWithBraces

New with 1.06. Makes the expansion of its argument and then reverses the resulting tokens or braced tokens, adding a pair of braces to each (thus, maintaining it when it was already there.) The reason for \xint:, here and in other locations, is in case #1 expands to nothing, the \romannumeral-`0 must be stopped

```

```

2.5 *\xintZapFirstSpaces*

1.09f, written [2013/11/01]. Modified (2014/10/21) for release 1.1 to correct the bug in case of an empty argument, or argument containing only spaces, which had been forgotten in first version. New version is simpler than the initial one. This macro does NOT expand its argument.

```

90 \def\xintZapFirstSpaces {\romannumeral0\xintzapfirstspaces }%
91 \def\xintzapfirstspaces#1{\long
92 \def\xintzapfirstspaces ##1{\XINT_zapbsp_a #1##1\xint:#1#1\xint:}%
93 }\xintzapfirstspaces{ }%

```

If the original #1 started with a space, the grabbed #1 is empty. Thus _again? will see #1=\xint_bye, and hand over control to _again which will loop back into \XINT_zapbsp_a, with one initial space less. If the original #1 did not start with a space, or was empty, then the #1 below will be a

<sptoken>, then an extract of the original #1, not empty and not starting with a space, which contains what was up to the first <sp><sp> present in original #1, or, if none preexisted, <sptoken> and all of #1 (possibly empty) plus an ending \xint:. The added initial space will stop later the \romannumeral0. No brace stripping is possible. Control is handed over to \XINT_zapbsp_b which strips out the ending \xint:<sp><sp>\xint:

```
94 \def\XINT_zapbsp_a#1{\long\def\XINT_zapbsp_a ##1#1#1{%
95   \XINT_zapbsp_again?##1\xint_bye\XINT_zapbsp_b ##1#1#1}%
96 }\XINT_zapbsp_a{ }%
97 \long\def\XINT_zapbsp_again? #1{\xint_bye #1\XINT_zapbsp_again }%
98 \xint_firstofone{\def\XINT_zapbsp_again\XINT_zapbsp_b} {\XINT_zapbsp_a }%
99 \long\def\XINT_zapbsp_b #1\xint:#2\xint:{#1}%
```

2.6 \xintZapLastSpaces

1.09f, written [2013/11/01].

```
100 \def\xintZapLastSpaces {\romannumeral0\xintzaplastspaces }%
101 \def\xintzaplastspaces#1{\long
102 \def\xintzaplastspaces ##1{\XINT_zapesp_a {} \empty##1#1\xint_bye\xint:{}}%
103 }\xintzaplastspaces{ }%
```

The \empty from \xintzaplastspaces is to prevent brace removal in the #2 below. The \expandafter chain removes it.

```
104 \xint_firstofone {\long\def\XINT_zapesp_a #1#2 } %<- second space here
105   {\expandafter\XINT_zapesp_b\expandafter{#2}{#1}}%
```

Notice again an \empty added here. This is in preparation for possibly looping back to \XINT_zapesp_a. If the initial #1 had no <sp><sp>, the stuff however will not loop, because #3 will already be <some spaces>\xint_bye. Notice that this macro fetches all way to the ending \xint:. This looks not very efficient, but how often do we have to strip ending spaces from something which also has inner stretches of _multiple_ space tokens ?;-).

```
106 \long\def\XINT_zapesp_b #1#2#3\xint:%
107   {\XINT_zapesp_end? #3\XINT_zapesp_e {#2#1}\empty #3\xint:{}}%
```

When we have been over all possible <sp><sp> things, we reach the ending space tokens, and #3 will be a bunch of spaces (possibly none) followed by \xint_bye. So the #1 in _end? will be \xint_bye. In all other cases #1 can not be \xint_bye (assuming naturally this token does not arise in original input), hence control falls back to \XINT_zapesp_e which will loop back to \XINT_zapesp_a.

```
108 \long\def\XINT_zapesp_end? #1{\xint_bye #1\XINT_zapesp_end }%
```

We are done. The #1 here has accumulated all the previous material, and is stripped of its ending spaces, if any.

```
109 \long\def\XINT_zapesp_end\XINT_zapesp_e #1#2\xint:{ #1}%
```

We haven't yet reached the end, so we need to re-inject two space tokens after what we have gotten so far. Then we loop.

```
110 \def\XINT_zapesp_e#1{%
111 \long\def\XINT_zapesp_e ##1{\XINT_zapesp_a {##1#1#1}}%
112 }\XINT_zapesp_e{ }%
```

2.7 \xintZapSpaces

1.09f, written [2013/11/01]. Modified for 1.1, 2014/10/21 as it has the same bug as \xintZapFirstSpaces. We in effect do first \xintZapFirstSpaces, then \xintZapLastSpaces.

```
113 \def\xintZapSpaces {\romannumeral0\xintzapspaces }%
114 \def\xintzapspaces#1{%
115 \long\def\xintzapspaces ##1% like \xintZapFirstSpaces.

```

2.9 \xintCSVtoList, \xintCSVtoListNonStripped

\xintCSVtoList transforms a,b,...,z into {a}{b}...{z}. The comma separated list may be a macro which is first f-expanded. First included in release 1.06. Here, use of \Z (and \R) perfectly safe.

[2013/11/02]: Starting with 1.09f, automatically filters items with \xintZapSpacesB to strip away all spaces around commas, and spaces at the start and end of the list. The original is kept as \xintCSVtoListNonStripped, and is faster. But ... it doesn't strip spaces.

```
141 \def\xintCSVtoList {\romannumeral0\xintcsvtolist }%
142 \long\def\xintcsvtolist #1{\expandafter\xintApply

2.10 *\xintListWithSep*

1.04. *\xintListWithSep* $\{\text{sep}\}\{\{a\}\{b\} \dots \{z\}\}$ returns a sep $b \text{sep} \dots \text{sep} z$. It f-expands its second argument. The 'sep' may be *\par*'s: the macro *\xintlistwithsep* etc... are all declared long. 'sep' does not have to be a single token. It is not expanded. The "list" argument may be empty.

\xintListWithSepNoExpand does not f-expand its second argument.

This venerable macro from 1.04 remained unchanged for a long time and was finally refactored at 1.2p for increased speed. Tests done with a list of identical *\x* items and a sep of *\z* demonstrated a speed increase of about:

- 3x for 30 items,
- 4.5x for 100 items,
- 7.5x--8x for 1000 items.

```

2.11 *\xintNthElt*

First included in release 1.06. Last refactored in 1.2j.

\xintNthElt {i}{List} returns the *i* th item from List (one pair of braces removed). The list is first f-expanded. The *\xintNthEltNoExpand* does no expansion of its second argument. Both variants expand *i* inside *\numexpr*.

With *i* = 0, the number of items is returned using *\xintLength* but with the List argument f-expanded first.

Negative values return the $|i|$ th element from the end.

When *i* is out of range, an empty value is returned.

```

2.12 *\xintKeep*

First included in release 1.09m.

\xintKeep{i}{L} f-expands its second argument L. It then grabs the first i items from L and discards the rest.

ATTENTION: **each such kept item is returned inside a brace pair** Use *\xintKeepUnbraced* to avoid that.

For i equal or larger to the number N of items in (expanded) L, the full L is returned (with braced items). For i=0, the macro returns an empty output. For i<0, the macro discards the first N-|i| items. No brace pairs added to the remaining items. For i is less or equal to -N, the full L is returned (with no braces added.)

\xintKeepNoExpand does not expand the L argument.

Prior to 1.2i the code proceeded along a loop with no pre-computation of the length of L, for the i>0 case. The faster 1.2i version takes advantage of novel *\xintLengthUpTo* from *xintkernel.sty*.

2.13 *\xintKeepUnbraced*

1.2a. Same as *\xintKeep* but will *not* add (or maintain) brace pairs around the kept items when $\text{length}(L)>i>0$.

The name may cause a mis-understanding: for $i<0$, (i.e. keeping only trailing items), there is no brace removal at all happening.

Modified for 1.2i like *\xintKeep*.

2.14 \xintTrim

First included in release 1.09m.

\xintTrim*i*{*L*} f-expands its second argument *L*. It then removes the first *i* items from *L* and keeps the rest. For *i* equal or larger to the number *N* of items in (expanded) *L*, the macro returns an empty output. For *i*=0, the original (expanded) *L* is returned. For *i*<0, the macro proceeds from the tail. It thus removes the last $|i|$ items, i.e. it keeps the first $N-|i|$ items. For $|i| \geq N$, the empty list is returned.

\xintTrimNoExpand does not expand the *L* argument.

Speed improvements with 1.2i for *i*<0 branch (which hands over to \xintKeep). Speed improvements with 1.2j for *i*>0 branch which gobbles items nine by nine despite not knowing in advance if it will go too far.

```

```

2.17 `\xintApplyUnbraced`

`\xintApplyUnbraced {\macro}{a}{b}...{z}` returns `\macro{a}...\macro{z}` where each instance of `\macro` is f-expanded using `\romannumeral-`0`. The second argument may be a macro as it is itself also f-expanded. No braces are added: this allows for example a non-expandable `\def` in `\macro`, without having to do `\gdef`. Introduced with release 1.06b.

2.22 **\xintApplyInline**

1.09a: `\xintApplyInline\macro{{a}{b}...{z}}` has the same effect as executing `\macro{a}` and then applying again `\xintApplyInline` to the shortened list `{b}...{z}` until nothing is left. This

is a non-expandable command which will result in quicker code than using `\xintApplyUnbraced`. It f-expands its second (list) argument first, which may thus be encapsulated in a macro.

Rewritten in 1.09c. Nota bene: uses catcode 3 Z as privated list terminator.

```

2.23 `\xintFor`, `\xintFor*`, `\xintBreakFor`, `\xintBreakForAndDo`

1.09c [2013/10/09]: a new kind of loop which uses macro parameters #1, #2, #3, #4 rather than macros; while not expandable it survives executing code closing groups, like what happens in an alignment with the & character. When inserted in a macro for later use, the # character must be doubled.

The non-star variant works on a csv list, which it expands once, the star variant works on a token list, which it (repeatedly) f-expands.

1.09e adds `\XINT_forever` with `\xintintegers`, `\xintdimensions`, `\xintrationals` and `\xintBreakFor`, `\xintBreakForAndDo`, `\xintIfForFirst`, `\xintIfForLast`. On this occasion `\xint_firstoftwo` and `\xint_secondeoftwo` are made long.

1.09f: rewrites large parts of `\xintFor` code in order to filter the comma separated list via `\xintCSVtoList` which gets rid of spaces. The #1 in `\XINT_for_forever?` has an initial space to-

ken which serves two purposes: preventing brace stripping, and stopping the expansion made by `\xintcsvtolist`. If the `\XINT_forever` branch is taken, the added space will not be a problem there.

1.09f rewrites (2013/11/03) the code which now allows all macro parameters from #1 to #9 in `\xintFor`, `\xintFor*`, and `\XINT_forever`. 1.2i: slightly more robust `\xintifForFirst/Last` in case of nesting.

2.24 \XINT_forever, \xintintegers, \xintdimensions, \xintrationals

New with 1.09e. But this used inadvertently `\xintiadd/\xintimul` which have the unnecessary `\xintnum` overhead. Changed in 1.09f to use `\xintiadd/\xintiimul` which do not have this overhead. Also 1.09f uses `\xintZapSpacesB` for the `\xintrationals` case to get rid of leading and ending spaces in the #4 and #5 delimited parameters of `\XINT_forever_opt_a` (for `\xintintegers` and `\xintdimensions` this is not necessary, due to the use of `\numexpr` resp. `\dimexpr` in `\XINT_?expr_Ua`, resp. `\XINT_?expr_Da`).

2.25 `\xintForpair`, `\xintForthree`, `\xintForfour`

1.09c.

[2013/11/02] 1.09f `\xintForpair` delegate to `\xintCSVtoList` and its `\xintZapSpacesB` the han-

dling of spaces. Does not share code with `\xintFor` anymore.

[2013/11/03] 1.09f: `\xintForpair` extended to accept #1#2, #2#3 etc... up to #8#9, `\xintForthree`, #1#2#3 up to #7#8#9, `\xintForfour` id.

1.2i: slightly more robust `\xintifForFirst/Last` in case of nesting.

```

2.26 `\xintAssign`, `\xintAssignArray`, `\xintDigitsOf`

`\xintAssign {a}{b}...{z}\to\A\B...\Z` resp. `\xintAssignArray {a}{b}...{z}\to\U.`
`\xintDigitsOf=\xintAssignArray.`

1.1c 2015/09/12 has (belatedly) corrected some "features" of `\xintAssign` which didn't like the case of a space right before the "`\to`", or the case with the first token not an opening brace and the subsequent material containing brace groups. The new code handles gracefully these situations.

2.27 CSV (non user documented) variants of Length, Keep, Trim, NthElt, Reverse

These routines are for use by `\xintListSel:x:csv` and `\xintListSel:f:csv` from `xintexpr`, and also for the `reversed` and `len` functions. Refactored for 1.2j release, following 1.2i updates to `\xintKQeep`, `\xintTrim`, ...

These macros will remain undocumented in the user manual:

-- they exist primarily for internal use by the `xintexpr` parsers, hence don't have to be general purpose; for example, they a priori need to handle only catcode 12 tokens (not true in `\xintNewExpr`, though) hence they are not really worried about controlling brace stripping (nevertheless 1.2j has paid some secondary attention to it, see below.) They are not worried about normalizing leading spaces either, because none will be encountered when the macros are used as auxiliaries to the expression parsers.

-- crucial design elements may change in future:

1. whether the handled lists must have or not have a final comma. Currently, the model is the one of comma separated lists with **no** final comma. But this means that there can not be a distinction of principle between a truly empty list and a list which contains one item which turns out to be empty. More importantly it makes the coding more complicated as it is needed to distinguish the empty list from the single-item list, both lacking commas.

For the internal use of `xintexpr`, it would be ok to require all list items to be terminated by a comma, and this would bring quite some simplifications here, but as initially I started with non-terminated lists, I have left it this way in the 1.2j refactoring.

2. the way to represent the empty list. I was tempted for matter of optimization and synchronization with `xintexpr` context to require the empty list to be always represented by a space token and to not let the macros admit a completely empty input. But there were complications so for the time being 1.2j does accept truly empty output (it is not distinguished from an input equal to a space token) and produces empty output for empty list. This means that the status of the «nil» object for the `xintexpr` parsers is not completely clarified (currently it is represented by a space token).

The original Python slicing code in `xintexpr` 1.1 used `\xintCSVtoList` and `\xintListWithSep{,}` to convert back and forth to token lists and apply `\xintKeep`/`\xintTrim`. Release 1.2g switched to devoted f-expandable macros added to `xinttools`. Release 1.2j refactored all these macros as a follow-up to 1.2i improvements to `\xintKeep`/`\xintTrim`. They were made `\long` on this occasion and auxiliary `\xintLengthUpTo:f:csv` was added.

Leading spaces in items are currently maintained as is by the 1.2j macros, even by `\xintNthEltPy:y:f:csv`, with the exception of the first item, as the list is f-expanded. Perhaps `\xintNthEltPy:f:csv` should remove a leading space if present in the picked item; anyway, there are no spaces for the lists handled internally by the Python slicer of `xintexpr`, except the «nil» object currently represented by exactly one space.

Kept items (with no leading spaces; but first item special as it will have lost a leading space due to f-expansion) will lose a brace pair under `\xintKeep:f:csv` if the first argument was positive and strictly less than the length of the list. This differs of course from `\xintKeep` (which always braces items it outputs when used with positive first argument) and also from `\xintKeepUnbraced` in the case when the whole list is kept. Actually the case of singleton list is special, and brace removal will happen then.

This behaviour was otherwise for releases earlier than 1.2j and may change again.

Directly usable names are provided, but these macros (and the behaviour as described above) are to be considered *unstable* for the time being.

2.27.1 `\xintLength:f:csv`

1.2g. Redone for 1.2j. Contrarily to `\xintLength` from `xintkernel.sty`, this one expands its argument.

```

2.27.3 *\xintKeep:f:csv*

1.2g 2016/03/17. Redone for 1.2j with use of *\xintLengthUpTo:f:csv*. Same code skeleton as *\xintKeep* but handling comma separated but non terminated lists has complications. The *\xintKeep* in case of a negative #1 uses *\xintgobble*, we don't have that for comma delimited items, hence we do a special loop here (this style of loop is surely competitive with *\xintgobble* for a few dozens items and even more). The loop knows before starting that it will not go too far.

```

```

This strange thing is in case the picked item was the last one, hence there was an ending `\xint:` (we could not put a comma earlier for matters of not confusing empty list with a singleton list), and we do this here to activate brace-stripping of item as all other items may be brace-stripped if picked. This is done for coherence. Of course, in the context of the `xintexpr.sty` parsers, there are no braces in list items...

```

2.27.9 Public names for the undocumented csv macros

Completely unstable macros: currently they expand the list argument and want no final comma. But for matters of *xintexpr.sty* I could as well decide to require a final comma, and then I could simplify implementation but of course this would break the macros if used with current functionalities.

Got split off from *xint* with release 1.1.

The core arithmetic routines have been entirely rewritten for release 1.2. The 1.2i and 1.2l brought again some improvements.

The commenting continues (2018/02/06) to be very sparse: actually it got worse than ever with release 1.2. I will possibly add comments at a later date, but for the time being the new routines are not commented at all.

3.1 Catcodes, ε - \TeX and reload detection

The code for reload detection was initially copied from HEIKO OBERDIEK's packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

```

3.3 (WIP!) Error conditions and exceptions

As per the Mike Cowlishaw/IBM's General Decimal Arithmetic Specification
<http://speleotrove.com/decimal/decarith.html>
and the Python3 implementation in its `Decimal` module.
`Clamped`, `ConversionSyntax`, `DivisionByZero`, `DivisionImpossible`, `DivisionUndefined`, `Inexact`, `InsufficientStorage`, `InvalidContext`, `InvalidOperation`, `Overflow`, `Inexact`, `Rounded`, `Subnormal`, `Underflow`.

X3.274 rajoute `LostDigits`
Python rajoute `FloatOperation` (et n'inclut pas `InsufficientStorage`)
quote de `decarith.pdf`: The `Clamped`, `Inexact`, `Rounded`, and `Subnormal` conditions can coincide with each other or with other conditions. In these cases then any trap enabled for another condition takes precedence over (is handled before) all of these, any `Subnormal` trap takes precedence over `Inexact`, any `Inexact` trap takes precedence over `Rounded`, and any `Rounded` trap takes precedence over `Clamped`.

WORK IN PROGRESS ! (1.21, 2017/07/26)

I follow the Python terminology: a trapped signal means it raises an exception which for us means an expandable error message with some possible user interaction. In this WIP state, the interaction is commented out. A non-trapped signal or condition would activate a (presumably silent) handler.

Here, no signal-raising condition is "ignored" and all are "trapped" which means that error handlers are never activated, thus left in garbage state in the code.

Various conditions can raise the same signal.

Only signals, not conditions, raise Flags.

If a signal is ignored it does not raise a Flag, but it activates the signal handler (by default now no signal is ignored.)

If a signal is not ignored it raises a Flag and then if it is not trapped it activates the handler of the `_condition_`.

If trapped (which is default now) an «exception» is raised, which means an expandable error message (I copied over the LaTeX3 code for expandable error messages, basically) interrupts the TeX run. In future, user input could be solicited, but currently this is commented out.

For now macros to reset flags are done but without public interface nor documentation.

Only four conditions are currently possibly encountered:

- `InvalidOperation`
- `DivisionByZero`
- `DivisionUndefined` (which signals `InvalidOperation`)
- `Underflow`

I did it quickly, anyhow this will become more palpable when some of the Decimal Specification is actually implemented. The plan is to first do the X3.274 norm, then more complete implementation will follow... perhaps...

Routines handling integers as lists of token digits

Routines handling big integers which are lists of digit tokens with no special additional structure.

Some routines do not accept non properly terminated inputs like "`\the\numexpr1`", or "`\the\mathcode`-`", others do.

These routines or their sub-routines are mainly for internal usage.

3.5 \XINT_cuz_small

`\XINT_cuz_small` removes leading zeroes from the first eight digits. Expands following `\romannumeral0`. At least one digit is produced.

```
126 \def\XINT_cuz_small#1{%
127 \def\XINT_cuz_small ##1##2##3##4##5##6##7##8%
128 {%
129   \expandafter#1\the\numexpr ##1##2##3##4##5##6##7##8\relax
130 }}\XINT_cuz_small{ }%
```

3.6 \xintNum

Very old routine got completely rewritten at 1.21.

New code uses `\numexpr` governed expansion and fixes some issues of former version particularly regarding inputs of the `\numexpr... \relax` type without `\the` or `\number` prefix, and/or possibly no terminating `\relax`.

\xintiNum{\numexpr 1}\foo in earlier versions caused premature expansion of \foo.

`\xintiNum{\the\numexpr 1}` was ok, but a bit luckily so.

Also, up to 1.2k inclusive, the macro fetched tokens eight by eight, and not nine by nine as is done now. I have no idea why.

```

131 \def\xintiNum {\romannumeral0\xintinum }%
132 \def\xintinum #1%
133 {%
134   \expandafter\XINT_num_cleanup\the\numexpr\expandafter\XINT_num_loop

```

Blocks of eight digits

The lingua of release 1.2.

3.19 `\XINT_cuz`

This (launched by `\romannumeral0`) iterately removes all leading zeroes from a sequence of 8N digits ended by `\R`.

Rewritten for 1.21, now uses `\numexpr` governed expansion and `\ifnum` test rather than delimited gobbling macros.

Note 2015/11/28: with only four digits the `gob_til_fourzeroes` had proved in some old testing faster than `\ifnum` test. But with eight digits, the execution times are much closer, as I tested back then.

```
385 \def\XINT_cuz #1{%
386 \def\XINT_cuz {\expandafter#1\the\numexpr\XINT_cuz_loop}%

395         \fi #9%
396 }%
397 \def\XINT_cuz_hitend\R #1\R{\relax}%
398 \def\XINT_cuz_cleantoend #1\R{\relax #1}%
```

3.20 `\XINT_cuz_byviii`

This removes eight by eight leading zeroes from a sequence of 8N digits ended by `\R`. Thus, we still have 8N digits on output. Expansion started by `\romannumeral0`

```
399 \def\XINT_cuz_byviii #1#2#3#4#5#6#7#8#9%
400 {%
401     \xint_gob_til_R #9\XINT_cuz_byviii_e \R
402     \xint_gob_til_eightzeroes #1#2#3#4#5#6#7#8\XINT_cuz_byviii_z 00000000%
403     \XINT_cuz_byviii_done #1#2#3#4#5#6#7#8#9%
404 }%
405 \def\XINT_cuz_byviii_z 00000000\XINT_cuz_byviii_done 00000000{\XINT_cuz_byviii}%
406 \def\XINT_cuz_byviii_done #1\R { #1}%
407 \def\XINT_cuz_byviii_e\R #1\XINT_cuz_byviii_done #2\R{ #2}%
```

3.21 `\XINT_unsep_loop`

This is used as

```
\the\numexpr0\XINT_unsep_loop (blocks of 1<8digits>!)
    \xint_bye!2!3!4!5!6!7!8!9!\xint_bye\xint_c_i\relax
```

It removes the 1's and !'s, and outputs the $8N$ digits with a 0 token as as prefix which will have to be cleaned out by caller.

Actually it does not matter whether the blocks contain really 8 digits, all that matters is that they have 1 as first digit (and at most 9 digits after that to obey the TeX-\numexpr bound).

Done at 1.21 for usage by other macros. The similar code in earlier releases was strangely in $O(N^2)$ style, apparently to avoid some memory constraints. But these memory constraints related to \numexpr chaining seems to be in many places in xint code base. The 1.21 version is written in the 1.2i style of \xintInc etc... and is compatible with some 1! block without digits among the treated blocks, they will disappear.

```
408 \def\xint_unsep_loop #1!#2!#3!#4!#5!#6!#7!#8!#9!%
409 {%
410   \expandafter\xint_unsep_clean

430 }}\xint_unsep_cuzsmall_x{ }%
```

3.23 \XINT_div_unsepQ

This is used by division to remove separators from the produced quotient. The quotient is produced in the correct order. The routine will also remove leading zeroes. An extra initial block of 8 zeroes is possible and thus if present must be removed. Then the next eight digits must be cleaned of leading zeroes. Attention that there might be a single block of 8 zeroes. Expansion launched by \romannumeral0.

Rewritten for 1.21 in 1.2i style.

```
431 \def\xint_div_unsepQ_delim {\xint_bye!2!3!4!5!6!7!8!9!\xint_bye\xint_c_i\relax\Z}%

533 }%
534 \def\xint_rev_nounsep_end\R\xint_rev_nounsep #1#2\W {\xint_rev_nounsep_done #1}%
535 \def\xint_rev_nounsep_done #1{ 1}%
```

3.32 `\XINT_unrevbyviii`

Used as `\romannumeral0\xint_unrevbyviii 1<8d>!....1<8d>!` terminated by

`1;!1\R!1\R!1\R!1\R!1\R!1\R!1\R!1\R!\W`

The `\romannumeral` in `unrevbyviii_a` is for special effects (expand some token which was put as `1<token>!` at the end of the original blocks). This mechanism is used by 1.2 subtraction (still true for 1.21).

```
536 \def\xint_unrevbyviii #11#2!1#3!1#4!1#5!1#6!1#7!1#8!1#9!%
537 {%
538     \xint_gob_til_R #9\xint_unrevbyviii_a\R
539     \XINT_unrevbyviii_a {#9#8#7#6#5#4#3#2#1}%
540 }%
541 \def\xint_unrevbyviii_a#1{%
542 \def\xint_unrevbyviii_a\R\xint_unrevbyviii ##1##2\W

544 }%
```

```
544 }\XINT_unrevbyviii_a{ }%
```

Can work with shorter ending pattern: $1; !1\!R!1\!R!1\!R!1\!R!1\!R!1\!R!$ but the longer one of `\XINT_unrevbyviii` is ok here too. Used currently (1.2) only by addition, now (1.2c) with long ending pattern. Does the final clean up of leading zeroes contrarily to general `\XINT_unrevbyviii`.

```
545 \def\XINT_smallunrevbyviii 1#1#2#1#3#1#4#1#5#1#6#1#7#1#8#9\W%
546 {%
547   \expandafter\XINT_cuz_small\xint_gob_til_sc #8#7#6#5#4#3#2#1%
548 }%
```

Core arithmetic

The four operations have been rewritten entirely for release 1.2. The new routines works with separated blocks of eight digits. They all measure first the lengths of the arguments, even addition and subtraction (this was not the case with `xintcore.sty` 1.1 or earlier.)

The technique of chaining `\the\numexpr` induces a limitation on the maximal size depending on the size of the input save stack and the maximum expansion depth. For the current (TL2015) settings (5000, resp. 10000), the induced limit for addition of numbers is at 19968 and for multiplication it is observed to be 19959 (valid as of 2015/10/07).

Side remark: I tested that `\the\numexpr` was more efficient than `\number`. But it reduced the allowable numbers for addition from 19976 digits to 19968 digits.

3.33 `\xintiiAdd`

1.21: `\xintiiAdd` made robust against non terminated input.

2 as first token of #1 stands for "no carry", 3 will mean a carry (we are adding 1<8digits> to
1<8digits>.) Version 1.2c has terminators of the shape 1;!, replacing the \Z! used in 1.2.
Call: \the\numexpr\XINT_add_a 2#11;!1;!1;!1;!W #21;!1;!1;!1;!W where #1 and #2 are blocks of
1<8d>!, and #1 is at most as long as #2. This last requirement is a bit annoying (if one wants to do
recursive algorithms but not have to check lengths), and I will probably remove it at some point.
Output: blocks of 1<8d>! representing the addition, (least significant first), and a final 1;!. In recursive algorithm this 1;! terminator can thus conveniently be reused as part of input terminator (up to the length problem).

3.35 *\xintiiSub*

Entirely rewritten for 1.2.

Refactored at 1.21. I was initially aiming at clinching some internal format of the type `1<8digits>!....1<8digits>!` for chaining the arithmetic operations (as a preliminary step to de-

cided upon some internal format for *xintfrac* macros), thus I wanted to uniformize delimiters in particular and have some core macros inputting and outputting such formats. But the way division is implemented makes it currently very hard to obtain a satisfactory solution. For subtraction I got there almost, but there was added overhead and, as the core sub-routine still assumed the shorter number will be positioned first, one would need to record the length also in the basic internal format, or add the overhead to not make assumption on which one is shorter. I thus but back-tracked my steps but in passing I improved the efficiency (probably) in the worst case branch.

Sadly this 1.21 refactoring left an extra ! in macro *\XINT_sub_l_Ida*. This bug shows only in rare circumstances which escaped out test suite :(Fixed at 1.2q.

The other reason for backtracking was in relation with the decimal numbers. Having a core format in base 10^8 but ultimately the radix is actually 10 leads to complications. I could use radix 10^8 for *\xintiiexpr* only, but then I need to make it compatible with sub-*\xintiiexpr* in *\xintexpr*, etc... there are many issues of this type.

I considered also an approach like in the 1.21 *\xintiiCmp*, but decided to stick with the method here for now.

                  #21;!1;!1;!1;!1\W

```

3 Package *xintcore* implementation

where #1 and #2 are blocks of $1<8d>!$, #1 (=B) *must* be at most as long as #2 (=A), (in radix 10^8) and the routine wants to compute $\#2 - \#1 = A - B$

1.21 uses $1;!$ delimiters to match those of addition (and multiplication). But in the end I reverted the code branch which made it possible to chain such operations keeping internal format in 8 digits blocks throughout.

$\backslash numexpr$ governed expansion stops with various possibilities:

- Type Ia: #1 shorter than #2, no final carry
- Type Ib: #1 shorter than #2, a final carry but next block of #2 > 1
- Type Ica: #1 shorter than #2, a final carry, next block of #2 is final and = 1
- Type Icb: as Ica except that 00000001 block from #2 was not final
- Type Id: #1 shorter than #2, a final carry, next block of #2 = 0
- Type IIa: #1 same length as #2, turns out it was $\leq \#2$.
- Type IIb: #1 same length as #2, but turned out $> \#2$.

Various type of post actions are then needed:

- Ia: clean up of zeros in most significant block of 8 digits

- Ib: as Ia

- Ic: there may be significant blocks of 8 zeros to clean up from result. Only case Ica may have arbitrarily many of them, case Icb has only one such block.

- Id: blocks of 99999999 may propagate and there might be final zero block created which has to be cleaned up.

- IIa: arbitrarily many zeros might have to be removed.

- IIb: We wanted $\#2 - \#1 = - (\#1 - \#2)$, but we got $10^{\{8N\}} + \#2 - \#1 = 10^{\{8N\}} - (\#1 - \#2)$. We need to do the correction then we are as in IIa situation, except that final result can not be zero.

The 1.21 method for this correction is (presumably, testing takes lots of time, which I do not have) more efficient than in 1.2 release.

```
887 \def\xint_sub_a #1!#2!#3!#4!#5\W #6!#7!#8!#9!%
888 {%

B terminated. Have we reached the end of A (necessarily at least as long as B) ? (we are computing A-B, digits of B come first).

If not, then we are certain that even if there is carry it will not propagate beyond the end of A. But it may propagate far transforming chains of 00000000 into 99999999, and if it does go to the final block which possibly is just 1<00000001>!, we will have those eight zeros to clean up.

If A and B have the same length (in base 10^8) then arbitrarily many zeros might have to be cleaned up, and if A<B, the whole result will have to be complemented first.

```

We need to add some extra delimiters at the end for post-action by `\XINT_num`, so we first grab the material up to `\W`

This is the case where both operands have same 10^8 -base length.

We were handling A-B but perhaps B>A. The situation with A=B is also annoying because we then have to clean up all zeros but don't know where to stop (if A>B the first non-zero 8 digits block would tell us when).

Here again we need to grab #3\W to position the actually used terminating delimiters.

Routines for post-processing after reversal, and removal of separators. It is a matter of cleaning up zeros, and possibly in the bad case to take a complement before that.

```
999 \def\xint_sub_fix_none;{\xint_cuz_small}%
1000 \def\xint_sub_fix_cuz ;{\expandafter\xint_num_cleanup\the\numexpr\xint_num_loop\%}
```

Case with A and B same number of digits in base 10^8 and $B > A$.

1.21 subtle chaining on the model of the 1.2i rewrite of \xintInc and similar routines. After taking complement, leading zeroes need to be cleaned up as in B<=A branch.

Call:

`\the\numexpr \xint_mul_loop 100000000!1;!W #11;!W #21;!`

where #1 and #2 are (globally reversed) blocks $1 < 8d > !$. Its is generally more efficient if #1 is the shorter one, but a better recipe is implemented in `\xint_mul_checklengths`. One may call `\xint_mul_loop` directly (but multiplication by zero will produce many $100000000!$ blocks on output).

Ends after having produced: $1 < 8d > ! \dots 1 < 8d > ! 1; !$. The last 8-digits block is significant one. It can not be $100000000!$ except if the loop was called with a zero operand.

Thus `\xint_mul_loop` can be conveniently called directly in recursive routines, as the output terminator can serve as input terminator, we can arrange to not have to grab the whole thing again.

```

1.2 small and mini multiplication in base 10^8 with carry. Used by the main multiplication routines. But division, float factorial, etc.. have their own variants as they need output with specific constraints.

The *minimulwc* has $1<8\text{digits carry}.<4\text{ high digits}.<4\text{ low digits!}<8\text{digits}>$.

It produces a block $1<8d>!$ and then jump back into \XINT_smallmul_a with the new 8digits carry as argument. The \XINT_smallmul_a fetches a new $1<8d>!$ block to multiply, and calls back \XINT_minimul_wc having stored the multiplicand for re-use later. When the loop terminates, the final carry is checked for being nul, and in all cases the output is terminated by a 1;!

Multiplication by zero will produce blocks of zeros.

```

3.37 *\xintiiDivision*

Completely rewritten for 1.2.

WARNING: some comments below try to describe the flow of tokens but they date back to xint 1.09j and I updated them on the fly while doing the 1.2 version. As the routine now works in base 10^8 , not 10^4 and "drops" the quotient digits, rather than store them upfront as the earlier code, I may well have not correctly converted all such comments. At the last minute some previously #1 became stuff like #1#2#3#4, then of course the old comments describing what the macro parameters stand for are necessarily wrong.

Side remark: the way tokens are grouped was not essentially modified in 1.2, although the situation has changed. It was fine-tuned in xint 1.0/1.1 but the context has changed, and perhaps I should revisit this. As a corollary to the fact that quotient digits are now left behind thanks to the chains of \numexpr, some macros which in 1.0/1.1 fetched up to 9 parameters now need handle less such parameters. Thus, some rationale for the way the code was structured has disappeared.

1.21: \xintiiDivision et al. made robust against non terminated input.

```
#1 = A, #2 = B. On calcule le quotient et le reste dans la division euclidienne de A par B: A=BQ+R,
0<= R < |B| .

Donc attention malgré son nom \XINT_div_prepare va jusqu'au bout. C'est donc en fait l'entrée principale (pour $B>0$, $A>0$) mais elle va regarder si B est $< 10^8$ et s'il vaut alors 1 ou 2, et si $A < 10^8$. Dans tous les cas le résultat est produit sous la forme $\{Q\}\{R\}$, avec Q et R sous leur forme final. On doit ensuite ajuster si le B ou le A initial était négatif. Je n'ai pas fait beaucoup d'efforts pour être un minimum efficace si A ou B n'est pas positif.

Special very small multiplication for division. We only need to cater for multiplicands from 1
to 9. The ending is different from standard verysmallmul, a zero carry is not suppressed. And no
final 1;! is added. If multiplicand is just 1 let's not forget to add the zero carry 100000000! at
the end.

Ici $B < 10^8$ (et est > 2). On exécute

$\expandafter\XINT_sdiv_out\the\numexpr\XINT_smalldivx_a \ x.1B!1<8d>!\dots1<8d>!1;$! avec $x = \text{round}(B/2)$, $1B=10^8+B$, et A déjà en blocs $1<8d>!$ (non renversés). Le $\the\numexpr\XINT_smalldivx_a$ va produire $Q\backslash Z R\backslash W$ avec un $R<10^8$, et un Q sous forme de blocs $1<8d>!$ terminé par $1!$ et nécessitant le nettoyage du premier bloc. Dans cette branche le B n'a pas été multiplié par une puissance de 10, il peut avoir moins de huit chiffres.

```

1691 \def\XINT_sdiv_out #1;!#2!%
1692     {\expandafter
1693     {\romannumeral0\XINT_unsep_cuzsmall

Cette routine fait la division euclidienne d'un nombre de seize chiffres par $#1 = C$ = diviseur sur huit chiffres $\geq 10^7$, avec $#2$ = sa moitié utilisée dans `\numexpr` pour contrebalancer l'arrondi (ARRRRRRGGGGHHHH) fait par $/$. Le nombre divisé $XY = X*10^8+Y$ se présente sous la forme $1<8chiffres>!1<8chiffres>!$ avec plus significatif en premier.

Seul le quotient est calculé, pas le reste. En effet la routine de division principale va utiliser ce quotient pour déterminer le "grand" reste, et le petit reste ici ne nous serait d'à peu près aucune utilité.

ATTENTION UNIQUEMENT UTILISÉ POUR DES SITUATIONS OÙ IL EST GARANTI QUE $X < C$! (et C au moins 10^7) le quotient euclidien de $X*10^8+Y$ par C sera donc $< 10^8$. Il sera renvoyé sous la forme $1<8chiffres>$.

An ending `1;!` is produced on output for `\XINT_mul_loop` and gets incorporated to the delimiter needed by the `\XINT_unrevbyviii` done by `\XINT_mul_out`.

3.46 \xintiiPow

The exponent is not limited but with current default settings of tex memory, with xint 1.2, the maximal exponent for 2^N is $N = 2^{17} = 131072$.

1.2f Modifies the initial steps: 1) in order to be able to let more easily \xintiPow use \xintNum on the exponent once xintfrac.sty is loaded; 2) also because I noticed it was not very well coded. And it did only a \numexpr on the exponent, contradicting the documentation related to the "i" convention in names.

1.2l: \xintiiPow made robust against non terminated input.

3.47 \xintiiFac

Moved here from xint.sty with release 1.2 (to be usable by \bnumexpr).

An `\xintiFac` is needed by `xintexpr.sty`. Prior to 1.2o it was defined here as an alias to `\xintiiFac`, then redefined by `xintfrac` to use `\xintNum`. This was incoherent. Contrarily to other similarly named macros, `\xintiiFac` uses `\numexpr` on its input. This is also incoherent with the naming scheme, alas.

Partially rewritten with release 1.2 to benefit from the inner format of the 1.2 multiplication.

With current default settings of the etex memory and a.t.t.o.w (11/2015) the maximal possible computation is 5971! (which has 19956 digits).

Note (end november 2015): I also tried out a quickly written recursive (binary split) implementation

and I was quite surprised that it was only about 1.6x--2x slower in the range N=200 to 2000 than the `\xintiiFac` here which attempts to be smarter...

Note (2017, 1.21): I found out some code comment of mine that the code here should be more in the style of `\xintiiBinomial`, but I left matters untouched.

1.2o modifies `\xintiFac` to be coherent with `\xintiBinomial`: only with `xintfrac.sty` loaded does it use `\xintNum`. It is documented only as macro of `xintfrac.sty`, not as macro of `xint.sty`.

With release 1.1 the core arithmetic routines \xintiiAdd, \xintiiSub, \xintiiMul, \xintiiQuo, \xintiiPow were separated to be the main component of the then new *xintcore*.

```

4.3 *\xintLen*

\xintLen gets extended to fractions by *xintfrac.sty*: A/B is given length *len(A)+len(B)-1* (somewhat arbitrary). It applies *\xintNum* to its argument. A minus sign is accepted and ignored.

For parallelism with *\xintiNum*/*\xintNum*, 1.2o defines *\xintiLen*.

```

```

4.4 \xintReverseDigits

1.2.

This puts digits in reverse order, not suppressing leading zeros after reverse. Despite lacking the "ii" in its name, it does not apply `\xintNum` to its argument (contrarily to `\xintLen`, this is not very coherent).

1.21 variant is robust against non terminated \the\numexpr input.

This macro is currently not used elsewhere in xint code.

4.5 \xintiiE

Originally was used in \xintiieexpr. Transferred from xintfrac for 1.1. Code rewritten for 1.2i. \xintiiE{x}{e} extends x with e zeroes if e is positive and simply outputs x if e is zero or negative. Attention, le comportement pour e < 0 ne doit pas être modifié car \xintMod et autres macros en dépendent.

```

105 \def\xintiiE {\romannumeral0\xintiiE }%
106 \def\xintiiE #1#2%

116 {\expandafter\XINT_dsx_append\romannumeral\XINT_rep #1\endcsname 0.%}
117 \def\XINT_iie_neg #1.#2;{ #2}%

```

le #2 a le bon pattern terminé par ; #1=0 est OK pour \XINT_rep.

4.6 \xintDecSplit

DECIMAL SPLIT

The macro \xintDecSplit {x}{A} cuts A which is composed of digits (leading zeroes ok, but no sign) (*) into two (each possibly empty) pieces L and R. The concatenation LR always reproduces A.

The position of the cut is specified by the first argument x. If x is zero or positive the cut location is x slots to the left of the right end of the number. If x becomes equal to or larger than the length of the number then L becomes empty. If x is negative the location of the cut is |x| slots to the right of the left end of the number.

(*) versions earlier than 1.2i first replaced A with its absolute value. This is not the case anymore. This macro should NOT be used for A with a leading sign (+ or -).

Entirely rewritten for 1.2i (2016/12/11).

Attention: \xintDecSplit not robust against non terminated second argument.

```

4.36 \xintifTrueAelseB, \xintifFalseAelseB

1.09i. 1.2i has removed deprecated \xintifTrueFalse, \xintifTrue.

1.2o uses \xintiiifNotZero, see comments to \xintAND etc... This will work fine with arguments being nested *xintfrac.sty* macros, without the overhead of \xintNum or \xintRaw parsing.

```

626 \def\xintifTrueAelseB {\romannumeral0\xintiiifnotzero}%
627 \def\xintifFalseAelseB{\romannumeral0\xintiiifzero}%

```

4.37 \xintIsTrue, \xintIsFalse

1.09c. Suppressed at 1.2o. They seem not to have been documented, fortunately.

```
628 \%let\xintIsTrue \xintIsNotZero
629 \%let\xintIsFalse\xintIsZero
```

4.38 \xintNOT

1.09c. But it should have been called \xintNOT, not \xintNot. Former denomination deprecated at 1.2o. Besides, the macro is now defined as ii-type.

```
630 \def\xintNot{\romannumeral0\XINT_signaldeprecated{xint}{xintNot}\xintiiiszero}%
631 \def\xintNOT{\romannumeral0\xintiiiszero}%
```

4.39 \xintAND, \xintOR, \xintXOR

Added with 1.09a. But they used \xintSgn, etc... rather than \xintiiSgn. This brings \xintNum overhead which is not really desired, and which is not needed for use by xintexpr.sty. At 1.2o I modify them to use only ii macros. This is enough for sign or zeroness even for xintfrac format, as manipulated inside the \xintexpr. Big hesitation whether there should be however \xintiiAND outputting 1 or 0 versus an \xintAND outputting 1[0] versus 0[0] for example.

```

4.40 \xintANDof

New with 1.09a. \xintANDof works also with an empty list. Empty items however are not accepted.

1.21 made \xintANDof robust against non terminated items.

1.2o's \xintifTrueAelseB is now an ii macro, actually.

This macro as well as ORof and XORof are actually not used by xintexpr, which has its own csv handling macros.

```

4.49 `\xintiisquareRoot`

First done with 1.08.

1.1 added `\xintiisquareRoot`.
 1.1a added `\xintiisqrtr`.

1.2f (2016/03/01-02-03) has rewritten the implementation, the underlying mathematics remaining about the same. The routine is much faster for inputs having up to 16 digits (because it does it all with `\numexpr` directly now), and also much faster for very long inputs (because it now fetches only the needed new digits after the first 16 (or 17) ones, via the geometric sequence 16, then 32, then 64, etc...; earlier version did the computations with all remaining digits after a suitable starting point with correct 4 or 5 leading digits). Note however that the fetching of tokens is via intrinsically $O(N^2)$ macros, hence inevitably inputs with thousands of digits start being treated less well.

Actually there is some room for improvements, one could prepare better input X for the upcoming treatment of fetching its digits by 16, then 32, then 64, etc...

Incidentally, as `\xintiiSqrt` uses subtraction and subtraction was broken from 1.2 to 1.2c, then for another reason from 1.2c to 1.2f, it could get wrong in certain (relatively rare) cases. There was also a bug that made it unnecessarily slow for odd number of digits on input.

1.2f also modifies `\xintFloatSqrt` in `xintfrac.sty` which now has more code in common with here and benefits from the same speed improvements.

1.2k belatedly corrects the output to `{1}{1}` and not 11 when input is zero. As braces are used in all other cases they should have been used here too.

Also, 1.2k adds an `\xintiSqrtR` macro, for coherence as `\xintiSqrt` is defined (and mentioned in user manual.)

4.51 *\xintiiBinomial*

2015/11/28-29 for 1.2f.

2016/11/19 for 1.2h: I truly can't understand why I hard-coded last year an error-message for arguments outside of the range for binomial formula. Naturally there should be no error but a rather a 0 return value for $\text{binomial}(x,y)$, if $y < 0$ or $x < y$!

I really lack some kind of infinity or NaN value.

1.2o deprecates xintiBinomial . (which xintfrac.sty redefined to use xintNum)

$y = x - k + 1, j = 1..k$. On va évaluer par $y/1 * (y+1)/2 * (y+2)/3$ etc... On essaie de regrouper de manière à utiliser au mieux numexpr . On peut aller jusqu'à $x=10000$ car $9999 * 10000 < 10^8$. $463 * 464 * 465 = 99896880$, $98 * 99 * 100 * 101 = 97990200$. On va vérifier à chaque étape si on dépasse un seuil. Le style de l'implémentation diffère de celui que j'avais utilisé pour xintiiFac . On pourrait tout-à-fait avoir une verybigloop, mais bon. Je rajoute aussi un verysmall. Le traitement est un peu différent pour elle afin d'aller jusqu'à $x=29$ (et pas seulement 26 si je suivais le modèle des autres, mais je veux pouvoir faire $\text{binomial}(29,1)$, $\text{binomial}(29,2)$, ... en vsmall).

y.j.k. La partie very small. y est au plus 26 (non 29 mais retesté dans \XINT_binom_vsmallloop_a), et tous les binomial(29,n) sont <10^8. On peut donc faire $y(y+1)(y+2)(y+3)$ et aussi il y a le fait que etex fait $a*b/c$ en double precision. Pour ne pas bifurquer à la fin sur smallloop, si n=27, 27, ou 29 on procède un peu différemment des autres boucles. Si je testais aussi #1 après #3-#2 pour les autres il faudrait des terminaisons différentes.

4.52 \xintiiPFactorial

2015/11/29 for 1.2f. Partial factorial pfac(a,b)=(a+1)...b, only for non-negative integers with a<=b<10^8.

1.2h (2016/11/20) removes the non-negativity condition. It was a bit unfortunate that the code raised `\xintError:OutOfRangePFac` if $0 \leq a \leq b < 10^8$ was violated. The rule now applied is to interpret `pfac(a,b)` as the product for $a < j \leq b$ (not as a ratio of Gamma function), hence if $a \geq b$, return 1 because of an empty product. If $a < b$: if $a < 0$, return 0 for $b \geq 0$ and $(-1)^{b-a}$ times $|b| \dots (|a|-1)$ for $b < 0$. But only for the range $0 \leq a \leq b < 10^8$ is the macro result to be considered as stable.

5 Package `xintbinhex` implementation

.1	Catcodes, ε - \TeX and reload detection	154	.6	<code>\xintDecToBin</code>	159
.2	Package identification	155	.7	<code>\xintHexToDec</code>	160
.3	Constants, etc...	155	.8	<code>\xintBinToDec</code>	162
.4	Helper macros	156	.9	<code>\xintBinToHex</code>	163
.4.1	<code>\XINT_zeroes_foriv</code>	156	.10	<code>\xintHexToBin</code>	164
.5	<code>\xintDecToHex</code>	156	.11	<code>\xintCHexToBin</code>	164

The commenting is currently (2018/02/06) very sparse.

The macros from 1.08 (2013/06/07) remained unchanged until their complete rewrite at 1.2m (2012/07/31).

At 1.2n dependencies on `xintcore` were removed, so now the package loads only `xintkernel` (this could have been done earlier).

Also at 1.2n, macros evolved again, the main improvements being in the increased allowable sizes of the input for `\xintDecToHex`, `\xintDecToBin`, `\xintBinToHex`. Use of `\csname` governed expansion at some places rather than `\numexpr` with some clean-up after it.

5.1 Catcodes, ε - \TeX and reload detection

The code for reload detection was initially copied from Heiko Oberdiek's packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

```

135   #5#6#7#8!\XINT_dthb_exclam\relax\XINT_dthb_nextfour #9%
136 }%

```

The 1.2n inserted exclamations marks, which when bumping back from \XINT_dthb_again gave rise to a \numexpr-loop which gathered the ! delimited arguments and inserted \expandafter\XINT_dthb_update\the\numexpr dynamically. The 1.2o trick is to insert it here immediately. Then at \XINT_dthb_again the \numexpr will trigger an already prepared chain.

The crux of the thing is handling of #3 at \XINT_dthb_update_a.

```

137 \def\XINT_dthb_exclam {!\XINT_dthb_exclam\relax
138           \expandafter\XINT_dthb_update\the\numexpr}%

148 }%

```

1.2m and 1.2n had some unduly complicated ending pattern for \XINT_dthb_nextfour as inheritance of a loop needing ! separators which was pruned out at 1.2o (see previous comment).

We only clean-up up to 3 zero hexadecimal digits, as output was produced in chunks of 4 hex digits. If input had no leading zero, output will have none either. If input had many leading zeroes, output will have some number (unspecified, but a recipe can be given...) of leading zeroes...

The coding is for varying a bit, I did not check if efficient, it does not matter.

5.7 *\xintHexToDec*

Completely (and belatedly) rewritten at 1.2m in the 1.2 style.

1.2m version robust against non terminated inputs, but there is no primitive from TeX which may generate hexadecimal digits and provoke expansion ahead, afaik, except of course if decimal digits are treated as hexadecimal. This robustness is not on purpose but from need to expand argument and then grab it again. So we do it safely.

Increased maximal size at 1.2n.

1.2m version robust against non terminated inputs.

An input without leading zeroes gives an output without leading zeroes.

```

It is a bit annoying to grab all to the end here. I have a version, modeled on the 1.2n variant of `\xintDecToHex` which solved that problem there, but it did not prove enough if at all faster in my brief testing and it had the defect of a reduced maximal allowed size of the input.

5.9 *\xintBinToHex*

Complete rewrite for 1.2m. But input for 1.2m version limited to about 13320 binary digits (expansion depth=10000).

Again redone for 1.2n for \csname governed expansion: increased maximal size.

Size of output is $\text{ceil}(\text{size}(\text{input})/4)$, leading zeroes in output (inherited from the input) are not trimmed.

An input without leading zeroes gives an output without leading zeroes.

Robust against non-terminated input.

```

5.10 `\xintHexToBin`

Completely rewritten for 1.2m.

Attention this macro is not robust against arguments expanding after themselves.

Only up to three zeros are removed on front of output: if the input had a leading zero, there will be a leading zero (and then possibly 4n of them if inputs had more leading zeroes) on output.

Rewritten again at 1.2n for \csname governed expansion.

5.11 `\xintCHexToBin`

The 1.08 macro had same functionality as `\xintHexToBin`, and slightly different code, the 1.2m version has the same code as `\xintHexToBin` except that it does not remove leading zeros from output: if the input had N hexadecimal digits, the output will have exactly 4N binary digits.

Rewritten again at 1.2n for \csname governed expansion.

6 Package *xintgcd* implementation

.1	Catcodes, ε - \TeX and reload detection	166	.7	\backslash xintBezoutAlgorithm	174
.2	Package identification	167	.8	\backslash xintGCDof	176
.3	\backslash xintGCD, \backslash xintiGCD	167	.9	\backslash xintLCMof	176
.4	\backslash xintLCM, \backslash xintiLCM	168	.10	\backslash xintTypesetEuclideanAlgorithm	176
.5	\backslash xintBezout	168	.11	\backslash xintTypesetBezoutAlgorithm	177
.6	\backslash xintEuclideanAlgorithm	172			

The commenting is currently (2018/02/06) very sparse. Release 1.09h has modified a bit the \backslash xintTypesetEuclideanAlgorithm and \backslash xintTypesetBezoutAlgorithm layout with respect to line indentation in particular. And they use the *xinttools* \backslash xintloop rather than the Plain \TeX or \LaTeX 's \backslash loop.

Since 1.1 the package only loads *xintcore*, not *xint*. And for the \backslash xintTypesetEuclideanAlgorithm and \backslash xintTypesetBezoutAlgorithm macros to be functional the package *xinttools* needs to be loaded explicitely by the user.

Breaking change at 1.2p: \backslash xintBezout{A}{B} formerly had output {A}{B}{U}{V}{D} with AU-BV=D, now it is {U}{V}{D} with AU+BV=D.

6.1 Catcodes, ε - \TeX and reload detection

The code for reload detection was initially copied from HEIKO OBERDIK's packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

6.3 *\xintGCD*, *\xintiiGCD*

1.09a added *\xintnum* filtering from *\xintiabs*. This is a bit overhead but makes it easier for the *gcd* function in *\xintexpr*.

1.1a defines *\xintiiGCD* to avoid overhead in *\xintiiexpr*.
 1.2p: but 1.2o deprecated *\xintiAbs*, and in fact *\xintGCD* should not have any *\xintNum* overhead for consistency with other *xint* macros. But well, it would be breaking change to modify this now. We can not use *\xintAbs* which will create a fraction A/1, so we use *\xintNum* directly.

6.5 *\xintBezout*

\xintBezout{#1}{#2} produces {U}{V}{D} with $UA+VB=D$, $D = \text{PGCD}(A, B)$ (non-positive), where #1 and #2 f-expand to big integers A and B.

I had not checked this macro for about three years when I realized in January 2017 that *\xintBezout{A}{B}* was buggy for the cases $A = 0$ or $B = 0$. I fixed that blemish in 1.21 but overlooked the

other blemish that `\xintBezout{A}{B}` with A multiple of B produced a coefficient U as -0 in place of 0.

Hence I rewrote again for 1.2p. On this occasion I modified the output of the macro to be $\{U\}\{V\}\{D\}$ with $AU+BV=D$, formerly it was $\{A\}\{B\}\{U\}\{V\}\{D\}$ with $AU - BV = D$. This is quite breaking change!

Note in particular change of sign of V.

I don't know why I had designed this macro to contain $\{A\}\{B\}$ in its output. Perhaps I initially intended to output $\{A//D\}\{B//D\}$ (but forgot), as this is actually possible from outcome of the last iteration, with no need of actually dividing. Current code however arranges to skip this last update, as U and V are already furnished by the iteration prior to realizing that the last non-zero remainder was found.

Also 1.2l raised `InvalidOperationException` if both A and B vanished, but I removed this behaviour at 1.2p.

We arrange for `\xintiiMul` sub-routine to be called only with positive arguments, thus skipping some un-needed sign parsing there. For that though we have to screen out the special cases A divides B, or B divides A. And we first want to exchange A and B if $A < B$. These special cases are the only one possibly leading to U or V zero (for A and B positive which is the case here.) Thus the general case always leads to non-zero U and V's and assigning a final sign is done simply adding a `-` to one of them, with no fear of producing `-0`.

We use the fact that the `\romannumeral-`0` (or equivalent) done by `\xintiiadd` will absorb the initial space token left by `\XINT_mul_plusplus` in its output.

We arranged for operands here to be always positive which is needed for `\XINT_mul_plusplus` entry point (last time I checked...). Admittedly this kind of optimization is not good for maintenance of code, but I can't resist temptation of limiting the shuffling around of tokens...

7.1 Catcodes, ε - \TeX and reload detection

The code for reload detection was initially copied from **HEIKO OBERDIEK**'s packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

```

7.6 *\XINT_outfrac*

Months later (2014/10/22): perhaps I should document what this macro does before I forget? from $\{e\}\{N\}\{D\}$ it outputs $N/D[e]$, checking in passing if $D=0$ or if $N=0$. It also makes sure D is not < 0 . I am not sure but I don't think there is any place in the code which could call *\XINT_outfrac* with a $D < 0$, but I should check.

```

```

7.7 *\XINT_inFrac*

Parses fraction, scientific notation, etc... and produces $\{n\}\{A\}\{B\}$ corresponding to A/B times 10^n . No reduction to smallest terms.

Extended in 1.07 to accept scientific notation on input. With lowercase e only. The *\xintexpr* parser does accept uppercase E also. Ah, by the way, perhaps I should at least say what this macro does? (belated addition 2014/10/22...), before I forget! It prepares the fraction in the internal format $\{\text{exponent}\}\{\text{Numerator}\}\{\text{Denominator}\}$ where Denominator is at least 1.

2015/10/09: this venerable macro from the very early days (1.03, 2013/04/14) has gotten a lifting for release 1.2. There were two kinds of issues:

- 1) use of \W, \Z, \T delimiters was very poor choice as this could clash with user input,
- 2) the new \XINT_frac_gen handles macros (possibly empty) in the input as general as \A.\Be\C/\D.\Ee\F.

The earlier version would not have expanded the \B or \E: digits after decimal mark were constrained to arise from expansion of the first token. Thus the 1.03 original code would have expanded only \A, \D, \C, and \F for this input.

This reminded me think I should revisit the remaining earlier portions of code, as I was still learning TeX coding when I wrote them.

Also I thought about parsing even faster the A/B[N] input, not expanding B, but this turned out to clash with some established uses in the documentation such as 1/\xintiiSqr{...}[0]. For the implementation, careful here about potential brace removals with parameter patterns such as like #1/#2#3[#4] for example.

While I was at it 1.2 added \numexpr parsing of the N, which earlier was restricted to be only explicit digits. I allowed [] with empty N, but the way I did it in 1.2 with \the\numexpr #1 was buggy, as it did not allow #1 to be a \count for example or itself a \numexpr (although such inputs were not previously allowed, I later turned out to use them in the code itself, e.g. the float factorial of version 1.2f). The better way would be \the\numexpr#1+\xint_c_ but 1.2f finally does only \the\numexpr #1 and #1 is not allowed to be empty.

The 1.2 \XINT_frac_gen had two locations with such a problematic \numexpr #1 which I replaced for 1.2f with \numexpr#1+\xint_c_.

Regarding calling the macro with an argument A[<expression>], a / in the expression must be suitably hidden for example in \firstofone type constructs.

Note: when the numerator is found to be zero \XINT_inFrac *always* returns {0}{0}{1}. This behaviour must not change because 1.2g \xintFloat and XINTinFloat (for example) rely upon it: if the denominator on output is not 1, then \xintFloat assumes that the numerator is not zero.

As described in the manual, if the input contains a (final) [N] part, it is assumed that it is in the shape A[N] or A/B[N] with A (and B) not containing neither decimal mark nor scientific part, moreover B must be positive and A have at most one minus sign (and no plus sign). Else there will be errors, for example -0/2[0] would not be recognized as being zero at this stage and this could cause issues afterwards. When there is no ending [N] part, both numerator and denominator will be parsed for the more general format allowing decimal digits and scientific part and possibly multiple leading signs.

1.2l fixes frailty of \XINT_infrac (hence basically of all xintfrac macros) respective to non terminated \numexpr input: \xintRaw{\the\numexpr} for example. The issue was that \numexpr sees the / and expands what's next. But even \numexpr 1// for example creates an error, and to my mind this is a defect of \numexpr. It should be able to trace back and see that / was used as delimiter not as operator. Anyway, I thus fixed this problem belatedly here regarding \XINT_infrac.

7.8 *\XINT_fra_gen*

Extended in 1.07 to recognize and accept scientific notation both at the numerator and (possible) denominator. Only a lowercase e will do here, but uppercase E is possible within an *\xintexpr..relax*

Completely rewritten for 1.2 2015/10/10. The parsing handles inputs such as *\A.\B\c/\D.\Ee\f* where each of *\A*, *\B*, *\D*, and *\E* may need f-expansion and *\C* and *\F* will end up in *\numexpr*.

1.2f corrects an issue to allow *\C* and *\F* to be *\count* variable (or expressions with *\numexpr*): 1.2 did a bad *\numexpr0#1* which allowed only explicit digits for expanded #1.

```

7.26 *\xintTFrac*

1.09i, for *frac* in *\xintexpr*. And *\xintFrac* is already assigned. T for truncation. However, potentially not very efficient with numbers in scientific notations, with big exponents. Will have to think it again some day. I hesitated how to call the macro. Same convention as in *maple*, but some people reserve fractional part to *x - floor(x)*. Also, not clear if I had to make it negative (or zero) if *x < 0*, or rather always positive. There should be in fact such a thing for each rounding function, *trunc*, *round*, *floor*, *ceil*.

```

7.27 *\xintTrunc*, *\xintiTrunc*

1.2i release notes: ever since its inception this macro was stupid for a decimal input: it did not handle it separately from the general fraction case A/B[N] with B>1, hence ended up doing divisions by powers of ten. But this meant that nesting *\xintTrunc* with itself was very inefficient.

1.2i version is better. However it still handles B>1, N<0 via adding zeros to B and dividing with this extended B. A possibly more efficient approach is implemented in *\xintXTrunc*, but its logic is more complicated, the code is quite longer and making it f-expandable would not shorten it... I decided for the time being to not complicate things here.

7.31 \xintXTrunc

1.09j [2014/01/06] This is completely expandable but not f-expandable. Rewritten for 1.2i (2016/12/04):

- no more use of \xintiloop from xinttools.sty (replaced by \xintreplicate... from xintkernel.sty),

- no more use in 0>N>-D case of a dummy control sequence name via \csname...\endcsname
- handles better the case of an input already a decimal number

Need to transfer code comments into public dtx.

```

7.38 *\xintPow*

1.2f: to be coherent with the "i" convention *\xintipow* should parse also its exponent via *\xintNum* when *xintfrac.sty* is loaded. This was not the case so far. Cependant le problème est que le fait d'appliquer *\xintNum* rend impossible certains inputs qui auraient pu être générés par *\numexpr*. Le *\numexpr* externe est ici pour intercepter trop grand input.

```

7.60 Floating point macros

For a long time the float routines dating back to releases 1.07/1.08a (May-June 2013) were not modified.

Since 1.2f (March 2016) the four operations first round their arguments to `\xinttheDigits`-floats (or P-floats), not (`\xinttheDigits+2`)-floats or (P+2)-floats as was the case with earlier releases.

The four operations addition, subtraction, multiplication, division have always produced the correct rounding of the theoretical exact value to P or `\xinttheDigits` digits when the inputs are decimal numbers with at most P digits, and arbitrary decimal exponent part.

From 1.08a to 1.2j, `\xintFloat` (and `\XINTinFloat` which is used to parse inputs to other float macros) handled a fractional input A/B via an initial replacement to A'/B' where A' and B' were A and B truncated to Q+2 digits (where asked-for precision is Q), and then they correctly rounded A'/B' to Q digits. But this meant that this rounding of the input could differ (by up to one unit in the last place) from the correct rounding of the original A/B to the asked-for number of digits (which until 1.2f in uses as auxiliary to the macros for the basic operations was 2 more than the prevailing precision).

Since 1.2k all inputs are correctly rounded to the asked-for number of digits (this was, I think, the case in the 1.07 release -- there are no code comments -- but was, afaicr, not very efficiently done, and this is why the 1.08a release opted for truncation of the numerator and denominator.)

Notice that in float expressions, the / is treated as operator, hence the above discussion makes a difference only for the special input form `qfloat(A/B)` or for an `\xintexpr A/B\relax` embedded in the float expression, with A or B having more digits than the prevailing float precision.

Internally there is no inner representation of P-floats as such !!!!!

The input parser will again compute the length of the mantissa on each use !!! This is obviously something that must be improved upon before implementation of higher functions.

Currently, special tricks are used to quickly recognize inputs having no denominators, or fractions whose numerators and denominators are not too long compared to the target precision P, and in particular P-floats or quotients of two such.

Another long-standing issue is that float multiplication will first compute the 2P or 2P-1 digits of the exact product, and then round it to P digits. This is sub-optimal for large P particularly as the multiplication algorithm is basically the schoolbook one, hence worse than quadratic in the TeX implementation which has extra cost of fetching long sequences of tokens.

7.61 `\xintFloat`

1.2f and 1.2g brought some refactoring which resulted in faster treatment of decimal inputs. 1.2i dropped use of some old routines dating back to pre 1.2 era in favor of more modern `\xintDSRr` for rounding. Then 1.2k improves again the handling of denominators B with few digits.

But the main change with 1.2k is a complete rewrite of the B>1 case in order to achieve again correct rounding in all cases.

The original version from 1.07 (May 2013) computed the exact rounding to P digits for all inputs. But from 1.08 on (June 2013), the macro handled A/B input by first truncating both A and B to at most P+2 digits. This meant that decimal input (arbitrarily long, with scientific part) was correctly rounded, but in case of fractional input there could be up to 0.6 unit in the last place difference of the produced rounding to the input, hence the output could differ from the correct rounding.

Example with 16 digits (the default): `\xintFloat {1/17597472569900621233}`
with xintfrac 1.07: 5.682634230727187e-20
with xintfrac 1.08b--1.2j: 5.682634230727188e-20
with xintfrac 1.2k: 5.682634230727187e-20
The exact value is 5.682634230727187499924124...e-20, showing that 1.07 and 1.2k produce the correct rounding.

Currently the code ends in a more costly branch in about 1 case among 500, where it does some extra operations (a multiplication in particular). There is a free parameter delta (here set at

4), I have yet to make some numerical explorations, to see if it could be favorable to set it to a higher value (with delta=5, there is only 1 exceptional case in 5000, etc...).

I have always hesitated about the policy of printing 10.00...0 in case of rounding upwards to the next power of ten. Already since 1.2f \XINTinFloat always produced a mantissa with exactly P digits (except for the zero value). Starting with 1.2k, \xintFloat drops this habit of printing 10.00..0 in such cases. Side note: the rounding-up detection worked when the input A/B was with numerator A and denominator B having each less than P+2 digits, or with B=1, else, it could happen that the output was a power of ten but not detected to be a rounding up of the original fraction. The value was ok, but printed 1.0...0eN with P-1 zeroes, not 10.0...0e(N-1).

I decided it was not worth the effort to enhance the algorithm to detect with 100% fiability all cases of rounding up to next power of ten, hence 1.2k dropped this.

To avoid duplication of code, and any extra burden on \XINTinFloat, which is the macro used internally by the float macros for parsing their inputs, we simply make now \xintFloat a wrapper of \XINTinFloat.

7.62 \XINTinFloat, \XINTinFloatS

This routine is like `\xintFloat` but produces an output of the shape `A[N]` which is then parsed faster as input to other float macros. Float operations in `\xintfloatexpr... \relax` use internally this format.

It must be used in form `\XINTinFloat[P]{f}`: the optional `[P]` is mandatory.

Since 1.2f, the mantissa always has exactly `P` digits even in case of rounding up to next power of ten. This simplifies other routines.

1.2g added a variant `\XINTinFloatS` which, in case of decimal input with less than the asked for precision `P` will not add extra zeros to the mantissa. For example it may output `2[0]` even if `P=500`, rather than the canonical representation `200...000[-499]`. This is how `\xintFloatMul` and `\xintFloatDiv` parse their inputs, which speeds-up follow-up processing. But `\xintFloatAdd` and `\xintFloatSub` still use `\XINTinFloat` for parsing their inputs; anyway this will have to be changed again when inner structure will carry upfront at least the length of mantissa as data.

Each time `\XINTinFloat` is called it at least computes a length. Naturally if we had some format for floats that would be dispensed of...

something like `<letterP><length of mantissa>.mantissa.exponent, etc...` not yet.

Since 1.2k, `\XINTinFloat` always correctly rounds its argument, even if it is a fraction with very big numerator and denominator. See the discussion of `\xintFloat`.

7.63 *\xintPFloat*

1.1. This is a prettifying printing macro for floats.

The macro applies one simple rule: *x.yz...eN* will drop scientific notation in favor of pure decimal notation if $-5 \leq N \leq 5$. This is the default behaviour of Maple. The *N* here is as produced on output by *\xintFloat*.

Special case: the zero value is printed 0. (with a dot)

The coding got simpler with 1.2k as its *\xintFloat* always produces a mantissa with exactly *P* digits (no more 10.0...0e*N* annoying exception).

```

7.64 `\XINTinFloatFracdigits`

1.09i, for `frac` function in `\xintfloatexpr`. This version computes exactly from the input the fractional part and then only converts it into a float with the asked-for number of digits. I will have to think it again some day, certainly.

1.1 removes optional argument for which there was anyhow no interface, for technical reasons having to do with `\xintNewExpr`.

1.1a renames the macro as `\XINTinFloatFracdigits` (from `\XINTinFloatFrac`) to be synchronous with the `\XINTinFloatSqrt` and `\XINTinFloat` habits related to `\xintNewExpr` problems.

Note to myself: I still have to rethink the whole thing about what is the best to do, the initial way of going through `\xinttfrac` was just a first implementation.

```

```

7.65 `\xintFloatAdd`, `\XINTinFloatAdd`

First included in release 1.07.

1.09ka improved a bit the efficiency. However the add, sub, mul, div routines were provisory and supposed to be revised soon.

Which didn't happen until 1.2f. Now, the inputs are first rounded to P digits, not P+2 as earlier.

```

7.67 \xintFloatMul, \XINTinFloatMul

1.07.

Starting with 1.2f the arguments are rounded to the target precision P not P+2.

1.2g handles the inputs via \XINTinFloatS which will be more efficient when the precision is large and the input is for example a small constant like 2.

1.2k does a micro improvement to the way the macro passes over control to its output routine (former version used a higher level \xintE causing some extra un-needed processing with two calls to \XINT_infrac where one was amply enough).

```

7.68 \xintFloatDiv, \XINTinFloatDiv

1.07.

Starting with 1.2f the arguments are rounded to the target precision P not P+2.

1.2g handles the inputs via \XINTinFloatS which will be more efficient when the precision is large and the input is for example a small constant like 2.

The actual rounding of the quotient is handled via \xintfloat (or \XINTinfloatS).

1.2k does the same kind of improvement in \XINT_FL_div_b as for multiplication: earlier code was unnecessarily high level.

7.69 *xintFloatPow*, *XINTinFloatPow*

1.07: initial version. 1.09j has re-organized the core loop.

2015/12/07. I have hesitated to map \wedge in expressions to *xintFloatPow* rather than *xintFloatPower*. But for 1.234567890123456 to the power 2145678912 with P=16, using Pow rather than Power seems to bring only about 5% gain.

This routine requires the exponent x to be compatible with *\numexpr* parsing.

1.2f has rewritten the code for better efficiency. Also, now the argument A for A^x is first rounded to P digits before switching to the increased working precision (which depends upon x).

```

This ending is common with `\xintFloatPower`.

In the case of negative exponent we need to inverse the Q-digits mantissa. This requires no special attention now as 1.2k's `\xintFloat` does correct rounding of fractions hence it is easy to bound the total error. It can be checked that the algorithm after final rounding to the target precision computes a value Z whose distance to the exact theoretical will be less than $0.52 \text{ ulp}(Z)$ (and worst cases can only be slightly worse than $0.51 \text{ ulp}(Z)$).

In the case of the half-integer exponent (only via the expression interface,) the computation (which proceeds via `\XINTinFloatPowerH`) ends with a square root. This square root extraction is done with 3 guard digits (the power operations were done with more.) Then the value is rounded to the target precision. There is thus this rounding to 3 guard digits (in the case of negative exponent the reciprocal is computed before the square-root), then the square root is (computed with exact rounding for these 3 guard digits), and then there is the final rounding of this to the target precision. The total error (for positive as well as negative exponent) has been estimated to at worst possibly exceed slightly $0.5125 \text{ ulp}(Z)$, and at any rate it is less than $0.52 \text{ ulp}(Z)$.

7.70 `\xintFloatPower`, `\XINTinFloatPower`

1.07. The core loop has been re-organized in 1.09j for some slight efficiency gain. The exponent B is given to `\xintNum`. The $^$ in expressions is mapped to this routine.

Same modifications as in `\xintFloatPow` for 1.2f.

1.2f adds a special private macro for allowing half-integral exponents for use with $^$ within `\xintfloatexpr`. The exponent will be first truncated to either an integer or an half-integer. The macro is not for general use.

1.2k does anew this 1.2f handling of half-integer exponents for the `\xintfloatexpr` parser: with 1.2f's code the final square-root extraction was applied to a value already rounded to the target precision, unneedlessly losing precision.

```

```

First the special macro for use by the expression parser which checks if one raises to an half-integer exponent. This is always with XINTdigits precision. Rewritten for 1.2k in order for the final square root to keep three guard digits.

We have to be careful that exponent #2 is not constrained by TeX bound. And we must allow fractions. The 1.2k variant does a rounding to nearest integer of half-integer, 1.2f did a truncation rather (this is done after truncation of #2 to fixed point with one digit after mark.) We try to recognize quickly the case of integer exponent, for speed, but there is overhead of going through xintiTrunc1 .

Computations are done with Q blocks of eight digits. When a multiplication has a carry, hence creates Q+1 blocks, the least significant one is dropped. The goal is to compute an approximate value X' to the exact value X, such that the final relative error $(X-X')/X$ will be at most 10^{-P-1} with P the desired precision. Then, when we round X' to X'' with P significant digits, we can prove that the absolute error $|X-X''|$ is bounded (strictly) by $0.6 \text{ulp}(X'')$. ($\text{ulp} = \text{unit in the last (significant) place}$). Let N be the number of such operations, the formula for Q deduces from the previous explanations is that $8Q$ should be at least $P+9+k$, with k the number of digits of N (in base 10). Note that 1.2 version used $P+10+k$, for 1.2f I reduced to $P+9+k$. Also, k should be the number of digits of the number N of multiplications done, hence for $n \leq 10000$ we can take $N=n/2$, or $N/3$, or $N/4$. This is rounded above by numexpr and always an overestimate of the actual number of approximate multiplications done (the first ones are exact). (vérifier ce que je raconte, j'ai la

flemme là).

We then want $\text{ceil}((P+k+n)/8)$. Using \numexpr rounding division (ARRRRGGGHHHH), if m is a positive integer, $\text{ceil}(m/8)$ can be computed as $(m+3)/8$. Thus with $m=P+10+k$, this gives $Q<-(P+13+k)/8$. The routine actually computes $8(Q-1)$ for use in $\text{\XINT_FL_fac_addzeros}$.

With 1.2f the formula is $m=P+9+k$, $Q<-(P+12+k)/8$, and we use now $4=12-8$ rather than the earlier $5=13-8$. Whatever happens, the value computed in $\text{\XINT_FL_fac_increaseP}$ is at least 8. There will always be an extra block.

Note: with Digits:=32; Maple gives for 200!:

```
> factorial(200.);  
375  
0.78865786736479050355236321393218 10  
My 1.2f routine (and also 1.2) outputs:  
7.8865786736479050355236321393219e374  
and this is the correct rounding because for 40 digits it computes  
7.886578673647905035523632139321850622951e374
```

Maple's result (contrarily to *xint*) is thus not the correct rounding but still it is less than 0.6 ulp wrong.

This is the crucial ending. I note that I used here an `\ifnum` test rather than the `gob_til_eightzeroes` thing. Actually for eight digits there is much less difference than for only four.

The "carry" situation is marked by a final `!-1` rather than `!-2` for no-carry. (a `\numexpr` must be stopped, and leaving a `-` as delimiter is good as it will not arise earlier.)

7.72 `\xintFloatPFactorial`, `\XINTinFloatPFactorial`

2015/11/29 for 1.2f. Partial factorial `pfactorial(a,b)=(a+1)...b`, only for non-negative integers with $a \leq b < 10^8$.

1.2h (2016/11/20) now avoids raising `\xintError:OutOfRangePFac` if the condition $0 \leq a \leq b < 10^8$ is violated. Same as for `\xintiiPFactorial`.

```

```

See the comments for `\XINT_FL_pfac_increaseP`. Case of $b=a+1$ should be filtered out perhaps. We only needed here to copy the `\xintPFactorial` macros and re-use `\XINT_FL_fac_mul`/`\XINT_FL_fac_out`. Had to modify a bit `\XINT_FL_pfac_addzeroes`. We can enter here directly with `#3` equal to specify the precision (the calculated value before final rounding has a relative error less than $\#3.10^{-(#4-1)}$), and `#5` would hold the macro doing the final rounding (or truncating, if I make a `FloatTrunc` available) to a given number of digits, possibly not `#4`. By default the `#3` is 1, but `FloatBinomial` calls it with `#3=4`.

7.73 `\xintFloatBinomial`, `\XINTinFloatBinomial`

1.2f. We compute $\text{binomial}(x, y)$ as $\text{pfac}(x-y, x)/y!$, where the numerator and denominator are computed with a relative error at most $4.10^{-\{P-2\}}$, then rounded (once I have a float truncation, I will use truncation rather) to $P+3$ digits, and finally the quotient is correctly rounded to P digits. This will guarantee that the exact value X differs from the computed one Y by at most $0.6 \text{ulp}(Y)$. (2015/12/01).

2016/11/19 for 1.2h. As for `\xintiiBinomial`, hard to understand why last year I coded this to raise an error if $y < 0$ or $y > x$! The question of the Gamma function is for another occasion, here x and y must be (small) integers.

7.74 \xintFloatSqrt , \XINTinFloatSqrt

First done for 1.08.

The float version was developed at the same time as the integer one and even a bit earlier. As a result the integer variant had some sub-optimal parts. Anyway, for 1.2f I have rewritten the integer variant, and the float variant delegates all preparatory work for it until the last step. In particular the very low precisions are not penalized anymore from doing computations for at least 17 or 18 digits. Both the large and small precisions give quite shorter computation times.

Also, after examining more closely the achieved precision I decided to extend the float version in order for it to obtain the correct rounding (for inputs already of at most P digits with P the precision) of the theoretical exact value.

Beyond about 500 digits of precision the efficiency decreases swiftly, as is the case generally speaking with *xintcore/xint/xintfrac* arithmetic macros.

Final note: with 1.2f the input is always first rounded to P significant places.

```

7.75 `\xintFloatE`, `\XINTinFloatE`

1.07: The fraction is the first argument contrarily to `\xintTrunc` and `\xintRound`.

1.2k had to rewrite this since there is no more a `\XINT_float_a` macro. Attention about `\XINTinFloatE`: it is for use by `xintexpr.sty`, contrarily to other `\XINTinFloat<foo>` macros it inserts itself the `[\XINTdigits]` thing, and with value 0 it produces on output `0[N]`, not `0[0]`.

```

8.1 Catcodes, ε - \TeX and reload detection

The code for reload detection was initially copied from **HEIKO OBERDIEK**'s packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

```

8.5 *\xintPowerSeries*

The 1.03 version was very lame and created a build-up of denominators. (this was at a time *\xintAdd* always multiplied denominators, by the way) The Horner scheme for polynomial evaluation is used in 1.04, this cures the denominator problem and drastically improves the efficiency of the macro. Modified in 1.06 to give the indices first to a *\numexpr* rather than expanding twice. I just use *\the\numexpr* and maintain the previous code after that. 1.08a adds the forgotten optimization following that previous change.

```

8.7 *\xintRationalSeries*

This computes $F(a) + \dots + F(b)$ on the basis of the value of $F(a)$ and the ratios $F(n)/F(n-1)$. As in *\xintPowerSeries* we use an iterative scheme which has the great advantage to avoid denominator build-up. This makes exact computations possible with exponential type series, which would be completely inaccessible to *\xintSeries*. #1=a, #2=b, #3=F(a), #4=ratio function Modified in 1.06 to give the indices first to a *\numexpr* rather than expanding twice. I just use *\the\numexpr* and maintain the previous code after that. 1.08a adds the forgotten optimization following that previous change.

8.8 *\xintRationalSeriesX*

a,b,initial,ratiofunction,x

This computes $F(a,x) + \dots + F(b,x)$ on the basis of the value of $F(a,x)$ and the ratios $F(n,x)/F(n-1,x)$. The argument *x* is first expanded and it is the value resulting from this which is used then throughout. The initial term $F(a,x)$ must be defined as one-parameter macro which will be given *x*. Modified in 1.06 to give the indices first to a *\numexpr* rather than expanding twice. I just use *\the\numexpr* and maintain the previous code after that. 1.08a adds the forgotten optimization following that previous change.

8.10 \xintFxPtPowerSeriesX

a,b,coeff,x,D

Modified in 1.06 to give the indices first to a `\numexpr` rather than expanding twice. I just use `\the\numexpr` and maintain the previous code after that. 1.08a adds the forgotten optimization following that previous change.

```

.29	<i>\xintGCToGC</i>	289

The commenting is currently (2018/02/06) very sparse. Release 1.09m (2014/02/26) has modified a few things: *\xintFtoCs* and *\xintCntoCs* insert spaces after the commas, *\xintCstoF* and *\xintCstoCv* authorize spaces in the input also before the commas, *\xintCntoCs* does not brace the produced coefficients, new macros *\xintFtoC*, *\xintCtoF*, *\xintCtoCv*, *\xintFGtoC*, and *\xintGGCFrac*.

There is partial dependency on *xinttools* due to *\xintCstoF* and *\xintCsToCv*.

9.1 Catcodes, ε - \TeX and reload detection

The code for reload detection was initially copied from HEIKO OBERDIEK's packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

9.17 xintCtoCv , xintCstoCv

1.09m uses xintCSVtoList on the argument of xintCstoCv to allow spaces also before the commas. The original xintCstoCv code became the one of the new xintCtoF dealing with a braced rather than comma separated list.

9.25 *\xintCntoCs*

Modified in 1.09m: added spaces after the commas in the produced list. Moreover the coefficients are not braced anymore. A slight induced limitation is that the macro argument should not contain some explicit comma (cf. *\XINT_cntcs_exit_b*), hence *\xintCntoCs* {*\macro*,} with *\def\macro,#1{<stuff>}* would crash. Not a very serious limitation, I believe.

9.26 *\xintCntoGC*

Modified in 1.06 to give the N first to a *\numexpr* rather than expanding twice. I just use *\the\numexpr* and maintain the previous code after that.

1.09m maintains the braces, as the coeff are allowed to be fraction and the slash can not be naked in the GC format, contrarily to what happens in *\xintCntoCs*. Also the separators given to *\xintGCToGCx* may then fetch the coefficients as argument, as they are braced.

This is release 1.2q of [2018/02/06].

10.1 Old comments

These general comments were last updated at the end of the 1.09x series in 2014. The principles remain in place to this day but refer to [CHANGES.html](#) for some significant evolutions since.

The first version was released in June 2013. I was greatly helped in this task of writing an expandable parser of infix operations by the comments provided in `13fp-parse.dtx` (in its version as available in April–May 2013). One will recognize in particular the idea of the ‘until’ macros; I have not looked into the actual `13fp` code beyond the very useful comments provided in its documentation.

A main worry was that my data has no a priori bound on its size; to keep the code reasonably efficient, I experimented with a technique of storing and retrieving data expandably as *names* of control sequences. Intermediate computation results are stored as control sequences `\.=a/b[n]`.

Roughly speaking, the parser mechanism is as follows: at any given time the last found ‘operator’ has its associated `until` macro awaiting some news from the token flow; first `getnext` expands forward in the hope to construct some number, which may come from a parenthesized sub-expression, from some braced material, or from a digit by digit scan. After this number has been formed the next operator is looked for by the `getop` macro. Once `getop` has finished its job, `until` is presented with three tokens: the first one is the precedence level of the new found operator (which may be an end of expression marker), the second is the operator character token (earlier versions had here already some macro name, but in order to keep as much common code to `expr` and `floatexpr` common as possible, this was modified) of the new found operator, and the third one is the newly found number (which was encountered just before the new operator).

The `until` macro of the earlier operator examines the precedence level of the new found one, and either executes the earlier operator (in the case of a binary operation, with the found number and a previously stored one) or it delays execution, giving the hand to the `until` macro of the operator having been found of higher precedence.

A minus sign acting as prefix gets converted into a (unary) operator inheriting the precedence level of the previous operator.

Once the end of the expression is found (it has to be marked by a `\relax`) the final result is output as four tokens (five tokens since 1.09j) the first one a catcode 11 exclamation mark, the second one an error generating macro, the third one is a protection mechanism, the fourth one a printing macro and the fifth is `\.=a/b[n]`. The prefix `\xintthe` makes the output printable by killing the first three tokens.

10.2 Catcodes, ε-T_EX and reload detection

The code for reload detection was initially copied from HETKO OBERDIEK’s packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

10.4 Locking and unlocking

Some renaming and modifications here with release 1.2 to switch from using chains of `\romannumeral-`0` in order to gather numbers, possibly hexadecimals, to using a `\csname` governed expansion. In this way no more limit at 5000 digits, and besides this is a logical move because the `\xintexpr` parser is already based on `\csname...\endcsname` storage of numbers as one token.

The limitation at 5000 digits didn't worry me too much because it was not very realistic to launch computations with thousands of digits... such computations are still slow with 1.2 but less so now. Chains or `\romannumeral` are still used for the gathering of function names and other stuff which I have half-forgotten because the parser does many things.

In the earlier versions we used the `lockscan` macro after a chain of `\romannumeral-`0` had ended gathering digits; this uses has been replaced by direct processing inside a `\csname...\endcsname` and the macro is kept only for matters of dummy variables.

Currently, the parsing of hexadecimal numbers needs two nested `\csname...\endcsname`, first to gather the letters (possibly with a hexadecimal fractional part), and in a second stage to apply `\xintHexToDec` to do the actual conversion. This should be faster than updating on the fly the number (which would be hard for the fraction part....).

```

```

10.11 `\thexintexpr`, `\thexintiexpr`, `\thexintfloatexpr`, `\thexintiexpr`

New with 1.2h. I have been three years long very strict in terms of prefixing macros, but well.

```
100 \let\thexintexpr \xinttheexpr
101 \let\thexintiexpr \xinttheiexpr
102 \let\thexintfloatexpr\xintthefloatexpr
103 \let\thexintiexpr \xinttheiexpr
```

10.12 `\xintthecoords`

1.1 Wraps up an even number of comma separated items into pairs of TikZ coordinates; for use in the following way:

```
coordinates {\xintthecoords\xintfloatexpr ... \relax}
```

The crazyness with the `\csname` and `unlock` is due to TikZ somewhat STRANGE control of the TOTAL number of expansions which should not exceed the very low value of 100 !! As we implemented `\XINT_thecoords_b` in an "inline" style for efficiency, we need to hide its expansions.

Not to be used as `\xintthecoords\xintthefloatexpr`, only as `\xintthecoords\xintfloatexpr` (or `\xintiexpr` etc...). Perhaps `\xintthecoords` could make an extra check, but one should not accustom users to too loose requirements!

```

10.22 The integer or decimal number or hexa-decimal number or function name or variable name or special hacky things big parser

10.22.1	Integral part (skipping zeroes)	301
10.22.2	Fractional part	303
10.22.3	Scientific notation	303
10.22.4	Hexadecimal numbers	304
10.22.5	Parsing names of functions and variables	306

1.2 release has replaced chains of \romannumeral-`0 by \csname governed expansion. Thus there is no more the limit at about 5000 digits for parsed numbers.

In order to avoid having to lock and unlock in succession to handle the scientific part and adjust the exponent according to the number of digits of the decimal part, the parsing of this decimal part counts on the fly the number of digits it encounters.

There is some slight annoyance with `\xintiiexpr` which should never be given a [n] inside its `\csname.=<digits>\endcsname` storage of numbers (because its arithmetic uses the ii macros which know nothing about the [N] notation). Hence if the parser has only seen digits when hitting something else than the dot or e (or E), it will not insert a [0]. Thus we very slightly compromise the efficiency of `\xintexpr` and `\xintfloatexpr` in order to be able to share the same code with `\xintiiexpr`.

Indeed, the parser at this location is completely common to all, it does not know if it is working inside `\xintexpr` or `\xintiiexpr`. On the other hand if a dot or a e (or E) is met, then the (common) parser has no scruples ending this number with a [n], this will provoke an error later if that was within an `\xintiiexpr`, as soon as an arithmetic macro is used.

As the gathered numbers have no spaces, no pluses, no minuses, the only remaining issue is with leading zeroes, which are discarded on the fly. The hexadecimal numbers leading zeroes are stripped in a second stage by the `\xintHexToDec` macro.

With 1.2, `\xinttheexpr . \relax` does not work anymore (it did in earlier releases). There must be digits either before or after the decimal mark. Thus both `\xinttheexpr 1.\relax` and `\xinttheexpr .1\relax` are legal.

The ` syntax is here used for special constructs like `+(..), `*(..) where + or * will be treated as functions. Current implementation pick only one token (could have been braced stuff), thus here it will be + or *, and via `\XINT_expr_op_`` this into becomes a suitable `\XINT_{expr|iiexpr|flexpr}_func_+` (or `*`). Documentation of 1.1 said to use `+`(...), but `+(...)` is also valid. The opening parenthesis must be there, it is not allowed to come from expansion.

```

309 \def\xint_expr_scanint_endbycs#1#2\xint_expr_scanint_d{\endcsname #1}%

```

With 1.2d the tacit multiplication in front of a variable name or function name is now done with a higher precedence, intermediate between the common one of `*` and `/` and the one of `^`. Thus `x/2y` is like `x/(2y)`, but `x^2y` is like `x^2*y` and `2y!` is not `(2y)!` but `2*y!`.

Finally, 1.2d has moved away from the `_scan` macros all the business of the tacit multiplication in one unique place via `\XINT_expr_getop`. For this, the ending token is not first given to `\string` as was done earlier before handing over back control to `\XINT_expr_getop`. Earlier we had to identify the catcode 11 ! signaling a sub-expression here. With no `\string` applied we can do it in `\XINT_expr_getop`. As a corollary of this displacement, parsing of big numbers should be a tiny bit faster now.

Extended for 1.2l to ignore underscore character `_` if encountered within digits; so it can serve as separator for better readability.

10.22.4 Hexadecimal numbers

1.2d has moved most of the handling of tacit multiplication to `\XINT_expr_getop`, but we have to do some of it here, because we apply `\string` before calling `\XINT_expr_scanhexI_aa`. I do not insert the `*` in `\XINT_expr_scanhexI_a`, because it is its higher precedence variant which will be expected, to do the same as when a non-hexadecimal number prefixes a sub-expression. Tacit multiplication in front of variable or function names will not work (because of this `\string`).

Extended for 1.21 to ignore underscore character `_` if encountered within digits.

```

505 }%

```

This handles: 1) (indirectly) tacit multiplication by a variable in front a of sub-expression, 2) (indirectly) tacit multiplication in front of a \count etc..., 3) functions which are recognized via an encountered opening parenthesis (but later this must be disambiguated from variables with tacit multiplication) 4) 5) 6) 7) acceptable components of a variable or function names: @, underscore, digits, letters (or chars of category code letter.)

The short lived 1.2d which followed the even shorter lived 1.2c managed to introduce a bug here as it removed the check for catcode 11 !, which must be recognized if ! is not to be taken as part of a variable name. Don't know what I was thinking, it was the time when I was moving the handling of tacit multiplication entirely to the \xint_expr_getop side. Fixed in 1.2e.

I almost decided to remove the \ifcat\relax test whose rôle is to avoid the \string#1 to do something bad is the escape char is a digit! Perhaps I will remove it at some point ! I truly almost did it, but also the case of no escape char is a problem (\string\0, if \0 is a count ...)

The (indirectly) above means that via \xint_expr_func then \xint_expr_op_ one goes back to \xint_expr_getop then \xint_expr_getop_b which is the location where tacit multiplication is now centralized. This makes the treatment of tacit multiplication for situations such as <variable>\count or <variable>\xintexpr..\relax, perhaps a bit sub-optimal, but first the variable name must be gathered, second the variable must expand to its value.

```

```

Comments written 2015/11/12: earlier there was an `\ifcsname` test for checking if we had a variable in front of a `(`, for tacit multiplication for example in `x(y+z(x+w))` to work. But after I had implemented functions (that was yesterday...), I had the problem if was impossible to re-declare a variable name such as "f" as a function name. The problem is that here we can not test if the function is available because we don't know if we are in `expr`, `iiexpr` or `floatexpr`. The `\xint_c_xviii` causes all fetching operations to stop and control is handed over to the routines which will be `expr`, `iiexpr` ou `floatexpr` specific, i.e. the `\XINT_{expr|iiexpr|flexpr}_op_{`|_}` which are invoked by the `util_<op>_b` macros earlier in the stream. Functions may exist for one but not the two other parsers. Variables are declared via one parser and usable in the others, but naturally `\xintiiexpr` has its restrictions.

Thinking about this again I decided to treat a priori cases such as `x(...)` as functions, after having assigned to each variable a low-weight macro which will convert this into `_getop\.=<value of x>*(...)`. To activate that macro at the right time I could for this exploit the "onliteral" intercept, which is parser independent (1.2c).

This led to me necessarily to rewrite partially the `seq`, `add`, `mul`, `subs`, `iter` ... routines as now the variables fetch only one token. I think the thing is more efficient.

1.2c had `\def\xint_expr_func #1(#2{\xint_c_xviii #2{#1}}`

In `\XINT_expr_func` the `#2` is `_` if `#1` must be a variable name, or `#2=` if `#1` must be either a function name or possibly a variable name which will then have to be followed by tacit multiplication before the opening parenthesis.

The `\xint_c_xviii` is there because `_op_`` must know in which parser it works. Dispensious for `_`. Hence I modify for 1.2d.

```
518 \def\xint_expr_func #1(#2{\if _#2\xint_dothis\xint_expr_op_\fi
519           \xint_orthat{\xint_c_xviii #2}{#1}}%)
```

10.23 `\XINT_expr_getop`: finding the next operator or closing parenthesis or end of expression

Release 1.1 implements multi-character operators.

1.2d adds tacit multiplication also in front of variable or functions names starting with a letter, not only a `@` or a `_` as was already the case. This is for `(x+y)z` situations. It also applies higher precedence in cases like `x/2y` or `x/2@`, or `x/2max(3,5)`, or `x/2\xintexpr 3\relax`.

In fact, finally I decide that all sorts of tacit multiplication will always use the higher precedence.

Indeed I hesitated somewhat: with the current code one does not know if `\XINT_expr_getop` as invoked after a closing parenthesis or because a number parsing ended, and I felt distinguishing the two was unneeded extra stuff. This means cases like `(a+b)/(c+d)(e+f)` will first multiply the last two parenthesized terms.

The `!` starting a sub-expression must be distinguished from the post-fix `!` for factorial, thus we must not do a too early `\string`. In versions < 1.2c, the catcode 11 `!` had to be identified in all branches of the number or function scans. Here it is simply treated as a special case of a letter.

1.2q adds tacit multiplication in cases such as `(1+1)3` or `5!7!`

```

10.25.1 Square brackets for lists, the `!?` for omit and abort, and the `++` postfix construct

This is all very clever and only need setting some suitable precedence levels, if only I could understand what I did in 2014... just joking. Notice that `op_()` macros are defined here in the `\xintFor` loop.

There is some clever business going on here with the letter `a` for handling constructs such as `[3..5]*2` (I think...).

1.2c has replaced 1.1's private dealings with "`^C`" (which was done before dummy variables got implemented) by use of "`!?`". See discussion of `omit` and `abort`.

```
637 \expandafter\let\csname XINT_expr_precedence_]\endcsname\xint_c_i
638 \expandafter\let\csname XINT_expr_precedence_;\endcsname\xint_c_i
639 \let\XINT_expr_precedence_a \xint_c_xviii
640 \let\XINT_expr_precedence_!?\ \xint_c_ii
641 \expandafter\let\csname XINT_expr_precedence_++)\endcsname \xint_c_i
```

Comments added 2015/11/13 Here we have in particular the mechanism for post action on lists via `op_[]` The `precedence_[]` is the one of a closing parenthesis. We need the closing parenthesis to do its job, hence we can not define a `op_[]+` operator for example, as we want to assign it the precedence of addition not the one of closing parenthesis. The trick I used in 1.1 was to let the `op_[]` insert the letter `a`, this letter exceptionnally also being a legitimate operator, launch the `_getop` and let it find a `a*`, `a+`, `a/`, `a-`, `a^`, `a**` operator standing for `]*`, `]+`, `]/`, `]^`, `]**` postfix item by item list operator. I thought I had in mind an example to show that having defined `op_a` and `precedence_a` for the letter `a` caused a reduction in syntax for this letter, but it seems I am lacking now an example.

2015/11/18: for 1.2d I accelerate `\XINT_expr_op_[]` to jump over the `\XINT_expr_getop_a` which now does tacit multiplications also in front of letters, for reasons of things like, `(x+y)z`, hence

it must not see the "a". I could have used a catcode12 a possibly, but anyhow jumping straight to \XINT_expr_scanop_a skips a few expansion steps (up to the potential price of less conceptual programming if I change things in the future.)

```
642 \catcode`\. 11 \catcode`= 11 \catcode`+ 11
643 \xintFor #1 in {expr,flexpr,iexpr} \do {%
644   \expandafter\let\csname XINT_#1_op_)\endcsname \XINT_expr_getop
645   \expandafter\let\csname XINT_#1_op_;\endcsname \space
646   \expandafter\def\csname XINT_#1_op_]\endcsname ##1{\XINT_expr_scanop_a a##1}%
647   \expandafter\let\csname XINT_#1_op_a\endcsname \XINT_expr_getop
```

1.1 2014/10/29 did \expandafter\.=+\xintiCeil which transformed it into \romannumeral0\xinticeil, which seems a bit weird. This exploited the fact that dummy variables macros could back then pick braced material (which in the case at hand here ended being {\romannumeral0\xinticeil...}) and were submitted to two expansions. The result of this was to provide a not value which got expanded only in the first loop of the :_A and following macros of seq, iter, rseq, etc...

Anyhow with 1.2c I have changed the implementation of dummy variables which now need to fetch a single locked token, which they do not expand.

The `\xintiCeil` appears a bit dispensious, but I need the starting value in a `\numexpr` compatible form in the iteration loops.

```

648     \expandafter\def\csname XINT_#1_op_+\)\endcsname ##1##2\relax
649 {\expandafter\XINT_expr_foundend \expandafter
650     {\expandafter\.=+\csname .=\xintiCeil{\XINT_expr_unlock ##1}\endcsname }}%
651 }%
652 \catcode`_. 12 \catcode`= 12 \catcode`+ 12

```

1.2d adds the *** for tying via tacit multiplication, for example $x/2y$. Actually I don't need the _itself mechanism for ***, only a precedence.

```

653 \catcode` & 12
654 \xintFor* #1 in {{==}{<=}{>=}{!=}{&&}{||}{**}{//}{/}{...}{..[]}{.}{.}{.}{%}
655           {+[]}{-[]}{*[]}{/[}{**[]}{^[]}{a+}{a-}{a*}{a/}{a**}{a^}{%}
656           {[}{[}{]}{[}{:}{:}{]}{!}{?}{++}{++}{}}{***}
657   \do {\expandafter\def\csname XINT_expr_itself_#1\endcsname {\#1}}%
658 \catcode` & 7
659 \expandafter\let\csname XINT_expr precedence ***\endcsname \xint c viii

```

10.25.2 The |, &, xor, <, >, =, <=, >=, !=, //, /:, .., +, -, *, /, ^, ..[, and].. operators for expr, floatexpr and iexpr operators

1.2d needed some room between /, * and ^. Hence precedence for ^ is now at 9

10.26 Macros for list selectors: `[list][N]`, `[list][:b]`, `[list][a:]`, `[list][a:b]`

10.26.1	<code>\xintListSel:x:csv</code>	318
10.26.2	<code>\xintListSel:f:csv</code>	319
10.26.3	<code>\xintKeep:x:csv</code>	320
10.26.4	<code>\xintKeep:f:csv</code>	321
10.26.5	<code>\xintTrim:f:csv</code>	321
10.26.6	<code>\xintNthEltPy:f:csv</code>	321
10.26.7	<code>\xintLength:f:csv</code>	321
10.26.8	<code>\xintReverse:f:csv</code>	321

Python slicing was first implemented for 1.1 (27 octobre 2014). But it used `\xintCSVtoList` and `\xintListWithSep{,}` to convert back and forth to token lists for use of `\xintKeep`, `\xintTrim`, `\xintNthElt`. Not very efficient! Also `[list][a:b]` was Python like but not `[list][N]` which counted items starting at one, and returned the length for `N=0`.

Release 1.2g changed this so `[list][N]` now counts starting at zero and `len(list)` computes the number of items. Also 1.2g had its own f-expandable macros handling directly the comma separated lists. They are located into `xinttools.sty`.

1.2j improved the `xinttools.sty` macros and furthermore it made the Python slicing in expressions a bit more efficient still by exploiting in some cases that expansion happens in `\csname...\endcsname` and does not have to be f-expandable. But the f-expandable variants must be kept for use by `\xintNewExpr` and `\xintdeffunc`.

10.27 Macros for a..b list generation

10.27.1 \xintSeq::csv	322
10.27.2 \xintiSeq::csv	323

Ne produit que des listes d'entiers inférieurs à la borne de TeX ! mais sous la forme $N/1[0]$ en ce qui concerne \xintSeq::csv.

10.27.1 \xintSeq::csv

Commence par remplacer a par `ceil(a)` et b par `floor(b)` et renvoie ensuite les entiers entre les deux, possiblement en décroissant, et extrémités comprises. Si $a=b$ est non entier en obtient donc `ceil(a)` et `floor(a)`. Ne renvoie jamais une liste vide.

Note: le a..b dans \xintfloatexpr utilise cette routine.

10.28 Macros for a..[d]..b list generation

10.28.1	<i>\xintSeqA::csv</i> , <i>\xintiiSeqA::csv</i> , <i>\XINTinFloatSeqA::csv</i>	323
10.28.2	<i>\xintSeqB::csv</i>	324
10.28.3	<i>\xintiiSeqB::csv</i>	324
10.28.4	<i>\XINTinFloatSeqB::csv</i>	325

Contrarily to a..b which is limited to small integers, this works with a, b, and d (big) fractions. It will produce a «nil» list, if a>b and d<0 or a<b and d>0.

10.28.1 *\xintSeqA::csv*, *\xintiiSeqA::csv*, *\XINTinFloatSeqA::csv*

```

10.31 ? as two-way and ?? as three-way conditionals with braced branches

In 1.1, I overload ? with ??, as : will be used for list extraction, problem with (stuff)?{?(1)}{0} for example, one should put a space (stuff)?{ ?(1)}{0} will work. Small idiosyncrasy. (which has been removed in 1.2h, there is no problem anymore with (test)?{?(1)}{0}, however (test)?{?}{!}(x) is not accepted; but (test)?{?(x)}{!(x)} is or even with {?(){!()}x).)

syntax: ?{yes}{no} and ??{<0}{=0}{>0}.

The difficulty is to recognize the second ? without removing braces as would be the case with standard parsing of operators. Hence the ? operator is intercepted in \XINT_expr_getop_b.

1.2h corrects a bug in \XINT_expr_op_? which in context like (test)?{\foo}{bar} would provoke expansion of \foo, or also with (test)?{}{bar} would result in an error. The fix also solves the (test)?{?(1)}{0} issue mentioned above.

10.33 The A/B[N] mechanism

Releases earlier than 1.1 required the use of braces around A/B[N] input. The [N] is now implemented directly. *BUT* this uses a delimited macro! thus N is not allowed to be itself an expression (I could add it...). \xintE, \xintiiE, and \XINTinFloatE all put #2 in a \numexpr. But attention to the fact that \numexpr stops at spaces separating digits: \the\numexpr 3 + 7 9\relax gives 109\relax !! Hence we have to be careful.

\numexpr will not handle catcode 11 digits, but adding a \detokenize will suddenly make illicit for N to rely on macro expansion.

```

10.34 *\XINT_expr_op_`* for recognizing functions

The "onliteral" intercepts is for `bool`, `togl`, `protect`, ... but also for `add`, `mul`, `seq`, etc... Genuine functions have `expr`, `iexpr` and `fexpr` versions (or only one or two of the three).

With 1.2c "onliteral" is also used to disambiguate variables from functions. However as I use only a `\ifcsname` test, in order to be able to re-define a variable as function, I move the check for being a function first. Each variable name now has its `onliteral_<name>` associated macro which is the new way tacit multiplication in front of a parenthesis is implemented. This used to be decided much earlier at the time of `\XINT_expr_func`.

The advantage of our choices for 1.2c is that the same name can be used for a variable or a function, the parser will apply the correct interpretation which is decided by the presence or not of an opening parenthesis next.

```

1357 \def\xINT_tmpa #1#2#3{%
1358     \def #1##1%
1359     {%
1360         \ifcsname XINT_#3_func_##1\endcsname

1382 \def\xint_expr_onliteral_protect #1%
1383     {\expandafter\xint_expr_getop\csname .=\detokenize{\#1}\endcsname }%
```

10.36 The `break` function

`break` is a true function, the parsing via expansion of the succeeding material proceeded via `_oparen` macros as with any other function.

```
1384 \def\xint_expr_func_break #1#2#3%
1385     {\expandafter #1\expandafter #2\csname.=?\romannumeral`&&@\xint_expr_unlock #3\endcsname }%
1386 \let\xint_flexpr_func_break \xint_expr_func_break
1387 \let\xint_iexpr_func_break \xint_expr_func_break
```

10.37 The `qint`, `qfrac`, `qfloat` “functions”

New with 1.2. Allows the user to hand over quickly a big number to the parser, spaces not immediately removed but should be harmless in general.

```
1388 \def\xint_expr_onliteral_qint #1%
1389     {\expandafter\xint_expr_getop\csname .=\xintiNum{\#1}\endcsname }%
1390 \def\xint_expr_onliteral_qfrac #1%
1391     {\expandafter\xint_expr_getop\csname .=\xintRaw{\#1}\endcsname }%
1392 \def\xint_expr_onliteral_qfloat #1%
1393     {\expandafter\xint_expr_getop\csname .=\XINTinFloatdigits{\#1}\endcsname }%
```

10.38 `\XINT_expr_op__` for recognizing variables

The 1.1 mechanism for `\XINT_expr_var_<varname>` has been modified in 1.2c. The `<varname>` associated macro is now only expanded once, not twice. We arrive here via `\XINT_expr_func`.

```
1394 \def\xint_expr_op__ #1% op__ with two _'s
1395     {%
1396         \ifcsname XINT_expr_var_#1\endcsname

1405     }%
1406 \def\xint_expr_unknown_variable #1{\xintError:removed \xint_gobble_i {\#1}}%
1407 \let\xint_flexpr_op__ \XINT_expr_op__
1408 \let\xint_iexpr_op__ \XINT_expr_op__
```

10.39 User defined variables: `\xintdefvar`, `\xintdefiivar`, `\xintdeffloatvar`

1.1 An active : character will be a pain with our delimited macros and I almost decided not to use := but rather = as assignation operator, but this is the same problem inside expressions with the modulo operator /:, or with babel+frenchb with all high punctuation ?, !, :, ;.

Variable names may contain letters, digits, underscores, and must not start with a digit. Names starting with @ or un underscore are reserved.

Note (2015/11/11): although defined since october 2014 with 1.1, they were only very briefly mentioned in the user documentation, I should have expanded more. I am now adding functions to variables, and will rewrite entirely the documentation of *xintexpr.sty*.

1.2c adds the "onliteral" macros as we changed our tricks to disambiguate variables from functions if followed by a parenthesis, in order to allow function names to have precedence on variable names.

I don't issue warnings if a an attempt to define a variable name clashes with a pre-existing function name, as I would have to check expr, iiexpr and also floatexpr. And anyhow overloading a function name with a variable name is allowed, the only thing to know is that if an opening parenthesis follows it is the function meaning which prevails.

2015/11/13: I now first do an a priori complete expansion of #1, and then apply \detokenize to the result, and remove spaces.

2015/11/21: finally I do not detokenize the variable name. Because this complicated the \xintu-nassignvar if it did the same and we wanted to use it to redeclare a letter as dummy variable.

Documentation of 1.2d said that the tacit multiplication always was done with increased precedence, but I had not at that time made up my mind for the case of variable(stuff) and pushed to CTAN early because I need to fix the bug I had introduced in 1.2c which itself I had pushed to CTAN early because I had to fix the 1.2 bug with subtraction....

Finally I decide to do it indeed. Hence for 1.2e. This only impacts situations such as A/B(stuff), which are thus interpreted as A/(B*(stuff)).

1.2p (2017/12/01) extends \xintdefvar for simultaneous assignments to multiple variables.

10.41 seq and the implementation of dummy variables

10.41.1	All letters usable as dummy variables	332
10.41.2	omit and abort	333
10.41.3	The special variables @, @1, @2, @3, @4, @@, @@(1), ..., @@@, @@@@, ... for recursion	334
10.41.4	\XINT_expr_onliteral_seq	335
10.41.5	\XINT_expr_onliteral_seq_a	335
10.41.6	\XINT_isbalanced_a for \XINT_expr_onliteral_seq_a	335
10.41.7	\XINT_allexpr_func_seqx	336
10.41.8	Evaluation over list, \XINT_expr_seq:_a with break, abort, omit	336
10.41.9	Evaluation over ++ generated lists with \XINT_expr_seq:_A	337

All of seq, add, mul, rseq, etc... (actually all of the extensive changes from xintexpr 1.09n to 1.1) was done around June 15-25th 2014, but the problem is that I did not document the code enough, and I had a hard time understanding in October what I had done in June. Despite the lesson, again being short on time, I do not document enough my current understanding of the innards of the beast...

I added subs, and iter in October (also the [:n], [n:] list extractors), proving I did at least understand a bit (or rather could imitate) my earlier code (but don't ask me to explain \xintNewExpr !)

The \XINT_expr_onliteral_seq_a parses: "expression, variable=list)" (when it is called the opening (has been swallowed, and it looks for the ending one.) Both expression and list may themselves contain parentheses and commas, we allow nesting. For example "x^2, x=1..10)", at the end of seq_a we have {variable{expression}}{list}, in this example {x{x^2}}{1..10}, or more complicated "seq(add(y,y=1..x),x=1..10)" will work too. The variable is a single lowercase Latin letter.

The complications with \xint_c_xviii in seq_f is for the recurrent thing that we don't know in what type of expressions we are, hence we must move back up, with some loss of efficiency (superfluous check for minus sign, etc...). But the code manages simultaneously expr, fexpr and iexpr.

10.41.1 All letters usable as dummy variables

The nil variable was introduced in 1.1 but isn't used under that name. However macros handling a..[d]..b, or for seq with dummy variable where omit has omitted everything may in practice inject a nil value as current number.

1.2c has changed the way variables are disambiguated from functions and for this it has added here the definitions of \XINT_expr_onliteral_<name>.

In 1.1 a letter variable say X was acting as a delimited macro looking for !X{stuff} and then would expand the stuff inside a \csname.=... \endcsname. I don't think I used the possibilities this opened and the 1.2c version has stuff _already_ encapsulated thus a single token. Only one expansion, not two is then needed in \XINT_expr_op__.

I had to accordingly modify seq, add, mul and subs, but fortunately realized that the @, @1, etc... variables for rseq, rrseq and iter already had been defined in the way now also followed by the Latin letters as dummy variables.

The 1.2e `\XINT_expr_makedummy` was adjoined `\xintnewdummy` by 1.2k for a public interface. It should not be used with multi-letter argument. The add, mul, seq, etc... can only work with one-letter long dummy variable. And this will almost certainly not change.

Also 1.2e does the tacit multiplication `x(stuff)->x*(stuff)` in its higher precedence form. Things are easy now that variables always fetch a single already locked value `\.=<number>`.

The tacit multiplication in case of the ``nil'' variable doesn't make much sense but we do it anyhow.

```

10.41.2 omit and abort

June 24 and 25, 2014.

Added comments 2015/11/13:

Et la documentation ? on n'y comprend plus rien. Trop rusé.

```
\def\XINT_expr_var OMIT #1\relax !{1^C!{}{}{}.\.=!\relax !}
```

```
\def\XINT_expr_var ABORT #1\relax !{1^C!{}{}{}.\.=^!\relax !}
```

C'était accompagné de `\XINT_expr_precedence_`^C=0` et d'un hack au sein même des macros until de plus bas niveau.

Le mécanisme sioux était le suivant: `^C` est déclaré comme un opérateur de précédence nulle. Lorsque le parseur trouve un "omit" dans un seq ou autre, il va insérer dans le stream `\XINT_expr_getop` suivi du texte de remplacement. Donc ici on avait un `1` comme place holder, puis l'opérateur `^C`. Celui-ci étant de précédence zéro provoque la finalisation de tous les calculs antérieurs dans le sous-bareeval. Mais j'ai dû hacker le `until_end_b` (et le `until_`_b`) qui confronté à `^C`, va se relancer à zéro, le `getnext` va trouver le `!{}{}{}.\.=!` et ensuite il y aura `\relax`, et le résultat sera `\.=!` pour omit ou `\.=^` pour abort. Les routines des boucles seq, iter, etc... peuvent alors repérer le `!` ou `^` et agir en conséquence (un long paragraphe pour ne décrire que partiellement une ou deux lignes de codes...).

Mais `^C` a été fait alors que je n'avais pas encore les variables muettes. Je dois trouver autre chose, car `seq(2^C, C=1..5)` est alors impossible. De toute façon ce `^C` était à usage interne uniquement.

Il me faut un symbole d'opérateur qui ne rentre pas en conflit. Bon je vais prendre `!?`. Ensuite au lieu de hacker `until_end`, il vaut mieux lui donner précédence 2 (mais ça ne pourra pas marcher à l'intérieur de parenthèses il faut d'abord les fermer manuellement) et lui associer un simplement

un op spécial. Je n'avais pas fait cela peut-être pour éviter d'avoir à définir plusieurs macros. Le #1 dans la définition de \XINT_expr_op_!? est le résultat de l'évaluation forcée précédente.

Attention que les premier ! doivent être de catcode 12 sinon ils signalent une sous-expression qui déclenche une multiplication tacite.

```
1507 \edef\XINT_expr_var_omit #1\relax !{1\string !?\relax !}%
1508 \edef\XINT_expr_var_abort #1\relax !{1\string !?^\relax !}%
1509 \def\XINT_expr_op_!#1#2\relax {\expandafter\XINT_expr_foundend\csname .=#2\endcsname}%
1510 \let\XINT_iexpr_op_!#1\XINT_expr_op_!?
1511 \let\XINT_flexpr_op_!#1\XINT_expr_op_!?
```

10.41.3 The special variables @, @1, @2, @3, @4, @@, @@(1), ..., @@@, @@@(1), ... for recursion

October 2014: I had completely forgotten what the @@ etc... stuff were supposed to do: this is for nesting recursions! (I was mad back in June). @@(N) gives the Nth back, @@@(N) gives the Nth back of the higher recursion!

1.2c adds the needed "onliteral" now that tacit multiplication between a variable and a (has a new mechanism. 1.2e does this tacit multiplication with higher precedence.

For the record, the ~ has catcode 3 in this code.

10.41.8 Evaluation over list, *\XINT_expr_seq:_a* with break, abort, omit

The #2 here is ...bareeval <expression>\relax !<variable name>. The #1 is a comma separated list of values to assign to the dummy variable. The *\XINT_expr_seq_empty?* intervenes immediately after handling of firstvalue.

1.2c has rewritten to a large extent this and other similar loops because the dummy variables now fetch a single encapsulated token (apart from a good means to lose a few hours needlessly -- as I have had to rewrite and review most everything, this change could make the thing more efficient

if the same variable is used many times in an expression, but we are talking micro-seconds here anyhow.)

```

10.41.9 Evaluation over ++ generated lists with \xint_expr_seq:_A

This is for index lists generated by n++. The starting point will have been replaced by its ceil (added: in fact with version 1.1. the ceil was not yet evaluated, but _var<letter> did an expansion of what they fetch). We use \numexpr rather than \xintInc, hence the indexing is limited to small integers.

The 1.2c version of n++ produces a #1 here which is already a single \.=<value> token.

```

1629 \def\xint_expr_seq:_A +#1!%
1630     {\expandafter\xint_expr_seq_empty?\romannumeral0\xint_expr_seq:_D #1}%

```

10.42 add, mul

1.2c uses more directly the `\xintiiAdd` etc... macros and has `opxadd/opxmul` rather than a single `opx`. This is less conceptual as I use explicitly the associated macro names for `+`, `*` but this makes other things more efficient, and the code more readable.

```
1644 \def\xint_expr_onliteral_add
1645   {\expandafter\xint_expr_onliteral_add_f\romannumeral`&&@\xint_expr_onliteral_seq_a {}%}

10.44.3	\xint_expr_rseq:_a etc...	340
10.44.4	\xint_expr_rseq:_A etc...	340

When func_rseq has its turn, initial segment has been scanned by oparen, the ; mimicking the rôle of a closing parenthesis, and stopping further expansion. Notice that the ; is discovered during standard parsing mode, it may be for example {;} or arise from expansion as rseq does not use a delimited macro to locate it.

Here and in rrseq and iter, 1.2c adds also use of \xintthebareeval, etc...

10.45.3 \XINT_expr_iter:_a etc...	342
10.45.4 \XINT_expr_iter:_A etc...	342

Prior to 1.2g, the `iter` keyword was what is now called `iterr`, analogous with `rrseq`. Somehow I forgot an `iter` functioning like `rseq` with the sole difference of printing only the last iteration. Both `rseq` and `iter` work well with list selectors, as `@` refers to the whole comma separated sequence of the initial values. I have thus deliberately done the backwards incompatible renaming of `iter` to `iterr`, and the new `iter`.

```

10.48 Macros handling csv lists for functions with multiple comma separated arguments in expressions

10.48.1	<i>\xintANDof:csv</i>	347
10.48.2	<i>\xintORof:csv</i>	347
10.48.3	<i>\xintXORof:csv</i>	347
10.48.4	Generic csv routine	347
10.48.5	<i>\xintMaxof:csv, \xintiiMaxof:csv</i>	348
10.48.6	<i>\xintMinof:csv, \xintiiMinof:csv</i>	348
10.48.7	<i>\xintSum:csv, \xintiiSum:csv</i>	348
10.48.8	<i>\xintPrd:csv, \xintiiPrd:csv</i>	348
10.48.9	<i>\xintGCDof:csv, \xintLCMof:csv</i>	348
10.48.10	<i>\xintiiGCDof:csv, \xintiiLCMof:csv</i>	349
10.48.11	<i>\XINTinFloatdigits, \XINTinFloatSqrdigits, \XINTinFloatFacdigits</i>	349
10.48.12	<i>\XINTinFloatMaxof:csv, \XINTinFloatMinof:csv</i>	349
10.48.13	<i>\XINTinFloatSum:csv, \XINTinFloatPrd:csv</i>	349

These macros are used inside *\csname... \endcsname*. These things are not initiated by a *\romannumeral* in general, but in some cases they are, especially when involved in an *\xintNewExpr*. They will then be protected against expansion and expand only later in contexts governed by an initial *\romannumeral-`0*. There each new item may need to be expanded, which would not be the case in the use for the *_func_* things.

1.2g adds (to be continued)

10.48.1 \xintANDof:csv

1.09a. For use by \xintexpr inside \csname. 1.1, je remplace ifTrueAelseB par iiNotZero pour des raisons d'optimisations.

10.51 User defined functions: `\xintdeffunc`, `\xintdefiifunc`, `\xintdeffloatfunc`

1.2c (November 11-12, 2015). It is possible to overload a variable name with a function name (and conversely). The function interpretation will be used only if followed by an opening parenthesis, disabling the tacit multiplication usually applied to variables. Crazy things such as `add(f(f), f=1..10)` are possible if there is a function "f". Or we can use "e" both for an exponential function and the Euler constant.

2015/11/13: function candidates names first completely expanded, then detokenized and cleaned of spaces.

2015/11/21: no more `\detokenize` on the function names. Also I use `#1(#2)#3:=#4` rather than `#1(#2):=#3`. Ah, rather `#1(#2)#3:#4`, then I don't have to worry about active :.

2016/02/22: 1.2f la macro associée à la fonction ne débute plus par un `\romannumeral`, de toute façon est pour emploi dans `\csname..\endcsname`.

2016/03/08: 1.2f allows comma separated expressions; until then the user had to use explicit parentheses `\xintdeffunc foo(x,...):=(..., ..., ...)\relax`.

10.52 *\xintNewFunction*

1.2h (2016/11/20). Syntax is *\xintNewFunction{<name>}[nb of arguments]{expression with #1, #2, ... as in *\xintNewExpr*}*. This defines a function for all three parsers but the expression parsing is delayed until function execution. Hence the expression admits all constructs, contrarily to *\xintNewExpr* or *\xintdeffunc*.

10.53 *\xintNewExpr*, *\xintNewIExpr*, *\xintNewFloatExpr*, *\xintNewIIExpr*

10.53.1	<i>\xintApply::csv</i>	361
10.53.2	<i>\xintApply:::csv</i>	362
10.53.3	<i>\XINT_expr_RApply:::csv</i> , <i>\XINT_expr_LApply:::csv</i> , <i>\XINT_expr_RLApply:::csv</i>	362
10.53.4	Mysterious stuff	362
10.53.5	<i>\xintNewExpr</i> , ..., at last.	365

There was an *\xintNewExpr* already in 1.07 from May 2013, which was modified in September 2013 to work with the # macro parameter character, and then refactored into a more powerful version in June 2014 for 1.1 release of 2014/10/28. List handling causes special challenges, addressed by *\xintApply::csv*, *\xintApply:::csv*, ... next.

Comments finally added 2015/12/11 (with later edits):

The whole point is to expand completely macros when they have only numerical arguments and to inhibit this expansion if not. This is done in a recursive way: the catcode 12 ~ is used to register a macro name whose expansion must be inhibited. Any argument itself starting with such a ~ will force use of ~ for the macro which receives it.

In this context the catcode 12 \$ is used to signal a "virtual list" argument. It triggers insertion of *\xintApply::csv* or *\xintApply:::csv* for delayed handling later. This succeeds into handling inputs such as [#1..[#2]..#3][#4:#5]...

A final *\scantokens* converts the "~" prefixed names into real control sequences.

For this whole mechanism we need to have everything expressed using exclusively f-expandable macros. We avoid *\csname... \endcsname* like construct, but if absolutely needed perhaps we will do it ultimately.

For the iterating loops *seq*, *iter*, etc..., and dummy variables, we have no macros to our disposal to handle the case where the list of indices is not explicit. Moreover *omit*, *abort*, *break* can not work with non numerical data. Thus the whole mechanism is currently not applicable to them. It does work when the macro parameters (or variables for *\xintdeffunc*) do not intervene in the list of values to iterate over. But we can not delay expansion of dummy variables.

10.53.1 *\xintApply::csv*

```

1.2c adds optional logging. For this needed to pass to *_NewExpr_a* the macro name as parameter. And *_NewExpr* itself receives two new parameters to treat both *\xintNewExpr* and *\xintdeffunc*.

Up to and including 1.2c the definition was global. Starting with 1.2d it is done locally.

For the 1.2a release I replaced all *\romannumeral`0* by a fancier *\romannumeral`&&@* (with & of catcode 7). I got lucky here that it worked, despite @ being of catcode comment (anyhow *\input xintexpr.sty* would not have compiled if not, and I would have realized immediately). But to be honest I wouldn't have been 100% sure beforehand that &&@ worked also with @ comment character. I now know.

1.2d's *\xintNewExpr* makes a local definition. In earlier releases, the definition was global.
