1 Examples

Package `bnumexpr` provides `\thebnumexpr ... \relax` which is analogous to `\the\numexpr ... \relax`, while allowing arbitrarily big integers, powers, factorials, floored division, modulo, and comma separated expressions. Examples:

`\thebnumexpr 1_208_637_867_168*(2_187_917_891_279+3_109_197_072_870)\relax`

x

6402293732412744144160032

`\thebnumexpr (13_8089_1090-300_1890_2902)*(1083_1908_3901-109_8290_3890)\relax`

-2787514672889976289932

`\thebnumexpr (92_874_927_979**5-31_9792_7979**6)/30!\relax`

-4006240736596543944035189

`\thebnumexpr 30!/20!/21/22/23/24/25/(26*27*28*29)\relax`

30

`\thebnumexpr 13^50//12^50, 13^50/:12^50\relax`

54, 650556287901099025745221048683760161794567947140168553

```
\thebnumexpr 13^50/12^50, 12^50\relax
55, 910043815000214977332758527534256632492715260325658624

\thebnumexpr (1^10+2^10+3^10+4^10+5^10+6^10+7^10+8^10+9^10)^3\relax
118685075462698981700620828125

\thebnumexpr 100!/36^100\relax
219
```

2 Differences from `\numexpr`

Apart from the extension to big integers (i.e. exceeding the \TeX limit at 2147483647), and the added operators, there are a number of important differences between `\bnumexpr` and `\numexpr`:

1. one must use either `\thebnumexpr` or `\bnethe \bnumexpr` to get a printable result, as `\bnumexpr ... \relax` expands to a private format (using `\number` as prefix to `\bnumexpr` would only serve to trigger the expansion to the `\bnumexpr` private format, hence will raise a \TeX error),
2. one may embed directly (without `\bnethe`) a `\bnumexpr ... \relax` in another one (or in a `\xintexpr ... \relax`), but not in a `\numexpr ... \relax`; on the other hand a `\numexpr ... \relax` does not need to be prefixed by `\the` or `\number` inside `\bnethe \bnumexpr` or `\thebnumexpr`,
3. contrarily to `\numexpr`, the `\bnumexpr` parser stops only after having found (and swallowed) a mandatory ending `\relax` token,
4. in particular spaces between digits do not stop `\bnumexpr`, in contrast with `\numexpr`:

```
\the \numexpr 3 5+79\relax expands (in one step) to 35+79\relax
\thebnumexpr 3 5+79\relax expands (in two steps) to 114
```
5. one may do `\edef \tmp {\bnumexpr 1+2\relax }`, and then either use `\tmp` in another `\bnumexpr ... \relax`, or print it via `\bnethe \tmp`. The computation is done at the time of the `\edef` (and two expansion steps suffice). This is again in contrast with `\numexpr ... \relax` which, without `\the` (or `\number` or `\romannumeral`) as prefix would not expand inside an `\edef`,
6. expressions may be comma separated. On input, spaces are ignored, naturally, and on output the values are comma separated with a space after each comma,
7. `\bnumexpr -(1+1)\relax` is legal contrarily to `\numexpr -(1+1)\relax` which raises an error,

8. `\numexpr 2\cnta \relax` is illegal (with `\cnta` a `\count`-variable.) But `\bnumexpr 2\cnta \relax` is perfectly legal and will do the tacit multiplication,
9. more generally, tacit multiplication applies in front of parenthesized sub-expressions, or sub `\bnumexpr ... \relax` (or `\numexpr ... \relax`),
10. the underscore `_` is accepted within the digits composing a number and is silently ignored by `\bnumexpr`,
11. `\numexpr` accepts \TeX syntax for hexadecimal input "EF (or octal input '377), but currently `\bnumexpr` does not. This could possibly be added in future¹ (hexadecimal prefix " is part of the recognized `\xintiiexpr` syntax from `xintexpr` if `xintbinhex` is loaded.) In the meantime, one may encapsulate such inputs (obeying \TeX 's bound on numbers) into a sub `\numexpr ... \relax`.

An important thing to keep in mind is that if one has a calculation whose result is a small integer, acceptable by \TeX in `\ifnum` or count assignments, this integer produced by `\the\bnumexpr` is not self-delimiting, contrarily to a `\numexpr ... \relax` construct: the situation is exactly as with a `\the \numexpr ... \relax`, thus one may need to terminate the number to avoid premature expansion of following tokens; for example with the `\space` token.

The parser `\bnumexpr` is a scaled-down version of parser `\xintiiexpr` from package `xintexpr`. It lacks in particular boolean operators, square roots and other functions, variables, hexadecimal inputs, etc... it may be slightly faster when handling complicated expressions as it does not have to check so many things.

The documentation of `xintexpr` explains that there is an impact on the memory of \TeX (the string pool, the hash table) as each intermediate number is stored as a dummy control sequence name during processing. After thousands of evaluations with numbers having hundreds of digits, parts of the \TeX memory can become saturated and end the `latex|pdflatex` run, but the problem can be avoided via enlarged memory parameters for `pdftex`, as made possible by modern TeX installations. Anyhow, computations with thousands of digits take time, and this is probably a more stringent constraint.

If the same operations need to be repeated again and again tens of thousands of times on varying (big) numbers, the memory problem mentioned above may be avoided by using nested macros rather than `\bnumexpr` or `\xintexpr` expressions. Utility `\xintNewIIExpr` from package `xintexpr` can be used to construct the possibly very complicated nested macro from a given expression with the needed operators and usual `#1, #2, #3, ...` placeholders.

The ε - \TeX extensions are required (this is the default on all modern installations for `latex|pdflatex` and also for `xelatex|lualatex`).

¹It is only a matter of copying pasting relevant code from `xintexpr`, so depends upon user demands addressed to the author ;-).

3 Printing big numbers

LATEX will not split long numbers at the end of lines. I personally often use helper macros (not in the package) of the following type:

```
\def\allowsplits #1{\ifx #1\relax \else #1\hskip 0pt plus 1pt\relax  
                      \expandafter\allowsplits\fi}%  
\def\printnumber #1{\expandafter\allowsplits \romannumeral-`0#1\relax }%  
% \printnumber thus first ``fully'' expands its argument.
```

4 Expression syntax

It is the expected one with infix operators and parentheses, the recognized operators being `+`, `-`, `*`, `/` (rounded division), `^` (power), `**` (power), `//` (by default floored division), `/:` (the associated modulo) and `!` (factorial).²

The modulo `/:` is by default associated with the floored division `//`, but using `\bnumexprsetup{mod=...}` it can, like the other operators, be remapped to any macro of one's choice.

Different computations may be separated by commas. The whole expression is handled token by token, any component (digit, operator, parenthesis... even the ending `\relax`) may arise on the spot from macro expansions.

The precedence rules are the expected ones.

There is currently no user interface to change precedence levels. The three operators `/`, `//`, `/:` are at the same level of precedence as the multiplication `*`. The factorial postfix `!` has highest precedence. The minus signs inherit the precedence level of the previously encountered infix operators.

In case of equal precedence the operations are left-associative, hence:
`\thebnumexpr 2^3^4, (2^3)^4, 2^(3^4)\relax`

```
4096, 4096, 2417851639229258349412352
```

The underscore `_` can be used to separate digits in long numbers, for readability of the input.

5 Options

The sole package option is `custom`: it tells `bnumexpr` not to load package `xintcore`.

6 \bnumexprsetup

Package `bnumexpr` needs that some big integer engine provides the macros doing the actual computations. By default, it loads package `xintcore` (a subset of `xint`; version `1.2p` is required) and uses `\bnumexprsetup` in the following way:

```
\usepackage{xintcore}
\bnumexprsetup{add=\xintiiAdd, sub=\xintiiSub, mul=\xintiiMul,
              divround=\xintiiDivRound, div=\xintiiDivFloor,
              mod=\xintiiMod, pow=\xintiiPow, fac=\xintiiFac}
```

The keys given to `\bnumexprsetup` must be lowercased. If using `\bnumexprsetup`, it is not necessary to specify all keys, for example one can do `\bnumexprsetup{mul=\MyFasterMul}`, and only multiplication will be changed.

²Releases `1.2b` and earlier associated in the default configuration truncated division to `//`. This was changed at `1.2c` to stay in sync with `xintcore 1.2p`. For backwards compatibility, one may add to existing document `\bnumexprsetup{div=\xintiiDivTrunc, mod=\xintiiModTrunc}`.

Naturally it is up to the user to load the appropriate package for the alternative macros.

As per the macros which are the key values, they must have the following properties:

1. they must be completely expandable (in the sense of an `\edef` or a `\csname ... \endcsname`.)
2. they must fully expand their arguments first (in the sense of `\romannumeral -`0`.)
3. they must output a number with no leading zeros, at most one minus sign and no plus sign.

The first two items are truly mandatory, the last one may be not obeyed if the extra key `opp` is used with `\bnumexprsetup` to specify a suitable macro for the opposite of a number. This macro will be presented not with a braced argument but directly with a sequence of digits (either as gathered by the parser which skips leading zeros, or as produced by the other arithmetic macros and then there could be a minus, or even a plus if macros others than the ones from `xintcore` have been used). Thus, `opp` could identify a plus sign `+` upfront and then act adequately.³

Macro `\bnumexprsetup` can be used multiple times in the same document, thus allowing to switch math engines or to remap operators to some other arithmetic macros of the same math engine. Its effect obeys the local scope.

README: [Usage], [Installation], [License]

Usage

The package ``bnumexpr`` allows expandable computations with big integers and the four infix operators `+`, `-`, `*`, `/`` (which does rounded integer division) familiar from the ``\numexpr`` e-TeX parser.

Besides extending the scope to arbitrarily big numbers (and having a more complete syntax, for example `-(1)` is legal input), it adds the (by default) floored division operator `//``, and its associated modulo `/:``, the power operator `^`` (or equivalently `**``), and the factorial post-fix operator `!``. The space character as well as the underscore character `_`` both may serve to optionally separate digits in long numbers, for better readability of the input.

³see `\BNE_Op_opp` in the code for the default.

For example:

```
\thebnumexpr ( 92_874_927_979^5 - 31_9792_7979^6 ) / 30!\relax
expands (in two steps) to ` -4006240736596543944035189`.
```

The ` \relax` ending token is mandatory and will be removed as a result of the evaluation.

The expression parser is scaled-down from the ` \xinttheiiexpr... \relax` parser as provided by package `xintexpr`[^1]: it does not handle boolean operators, dummy or user defined variables, functions, etc...

By default the underlying arithmetic macros are the ones provided by package `xintcore`[^1] (its release 1.2 is required).

`bnumexpr` has only one option `_custom_` which says to not load `xintcore`, and a command ` \bnumexprsetup` to inform the package which macros to use if not those from `xintcore`.

Notice that the possibility not to use the `xintcore` macros might be removed in the future: perhaps a future release will maintain during computations a private internal representation (especially taylored either for the `xintcore` macros or new ones which would be included within ` `bnumexpr.sty`` itself) and the constraints this implies may render optional use of other macros impossible.

[^1]: <<http://www.ctan.org/pkg/xint>>

Installation

Obtain ` `bnumexpr.dtx`` (and possibly, ` `bnumexpr.ins`` and the ` `README``) from CTAN:

```
> <http://www.ctan.org/pkg/bnumexpr>
```

Both ` "tex `bnumexpr.ins`"` and ` "tex `bnumexpr.dtx`"` extract from ` `bnumexpr.dtx`` the following files:

- ` `bnumexpr.sty``
: this is the style file.
- ` `README.md``
: reconstitutes this README.
- ` `bnumexprchanges.tex``
: lists changes from the initial version.
- ` `bnumexpr.tex``
: can be used to generate the documentation:
 - : - with `latex+dvipdfmx`: ` "latex `bnumexpr.tex`"` (thrice) then ` "dvipdfmx `bnumexpr.dvi`"`.
 - : Ignore `dvipdfmx` warnings, but if the pdf file has problems with fonts (possibly from an old `dvipdfmx`), use then rather `pdflatex`.
 - : - with `pdflatex`: ` "pdflatex `bnumexpr.tex`"` (thrice).
- : In both cases files ` `README.md`` and ` `bnumexprchanges.tex`` must be present in the same repertory.

```
without `bnumexpr.tex`:  
: ``pdflatex bnumexpr.dtx`` (thrice) extracts all files and  
simultaneously generates the pdf documentation.
```

Finishing the installation:

```
bnumexpr.sty    --> TDS:tex/latex/bnumexpr/  
bnumexpr.dtx    --> TDS:source/latex/bnumexpr/  
bnumexpr.ins    --> TDS:source/latex/bnumexpr/  
bnumexpr.pdf    --> TDS:doc/latex/bnumexpr/  
README        --> TDS:doc/latex/bnumexpr/
```

Files `bnumexpr.tex`, `bnumexprchanges.tex`, `README.md` may be discarded.

8 Changes

1.2c (2017/12/05) Breaking changes:

- requires `xintcore 1.2p` or later (if not using option `custom`).
- `divtrunc` key of `\bnumexprsetup` is renamed to `div`.
- the `//` and `/:` operators are now by default associated to the *floored* division. This is to keep in sync with the change of `xintcore` at `1.2p`.
- for backwards compatibility, one may add to existing document:
`\bnumexprsetup{div=\xintiiDivTrunc, mod=\xintiiModTrunc}`

1.2b (2017/07/09)

- the `_` may be used to separate visually blocks of digits in long numbers.

- 1.2a (2015/10/14) • requires `xintcore 1.2` or later (if not using option `custom`).
- additions to the syntax: factorial `!`, truncated division `//`, its associated modulo `/:` and `**` as alternative to `^`.
 - all options removed except `custom`.
 - new command `\bnumexprsetup` which replaces the commands such as `\bnumexprusesbigintcalc`.
 - the parser is no more limited to numbers with at most 5000 digits.
- 1.1b (2014/10/28) • README converted to `markdown/pandoc` syntax,
- the package now loads only `xintcore`, which belongs to `xint` bundle version 1.1 and extracts from the earlier `xint` package the core arithmetic operations as used by `bnumexpr`.
- 1.1a (2014/09/22) • added `l3bigint` option to use experimental $\text{\LaTeX}3$ package of the same name,
- added Changes and Readme sections to the documentation,
 - better `\BNE_protect` mechanism for use of `\bnumexpr ... \relax` inside an `\edef` (without `\bnethe`). Previous one, inherited from `xintexpr.sty 1.09n`, assumed that the `\.=<digits>` dummy control sequence encapsulating the computation result had `\relax` meaning. But removing this assumption was only a matter of letting `\BNE_protect` protect two, not one, tokens. This will be backported to next version of `xintexpr`, naturally (done with `xintexpr.sty 1.1`).
- 1.1 (2014/09/21) First release. This is down-scaled from the (development version of) `xintexpr`. Motivation came the previous day from a chat with JOSEPH WRIGHT over big int status in $\text{\LaTeX}3$. The `\bnumexpr ... \relax` parser can be used on top of big int macros of one's choice. Functionalities limited to the basic operations. I leave the power operator `^` as an option.

9 Package *bnumexpr* implementation

Contents

9.2 Some helper macros and constants from <i>xint</i>	10
9.3 \bnumexprsetup	11
9.4 Package options	11
9.5 \bnumexpr, \bnethe, \thebnumexpr,	12
9.6 \BNE_getnext	12
9.7 Parsing an integer	13
9.8 \BNE_getop	14
9.9 Until macros for global expression and parenthesized sub-ones	15
9.10 The arithmetic operators.	16
9.11 ! as postfix factorial operator	17
9.12 The minus as prefix operator of variable precedence level	17
9.13 The comma may separate expressions.	18
9.14 Cleanup	19

Comments are sparse. Error handling by the parser is kept to a minimum; if something goes wrong, the offensive token gets discarded, and some undefined control sequence attempts to trigger writing to the log of some sort of informative message. It is recommended to set `\errorcontextlines` to at least 2 for more meaningful context.

9.1 Package identification and catcode setup

53   \bnumexprsetup{add=\xintiiAdd, sub=\xintiiSub, mul=\xintiiMul,
54                 divround=\xintiiDivRound, div=\xintiiDivFloor,
55                 mod=\xintiiMod, pow=\xintiiPow, fac=\xintiiFac}%
56 \fi
```

9.5 \bnumexpr, \bnethe, \thebnumexpr, ...

In the full `\xintexpr`, the final unlocking may involve post-treatment of the comma separated values, hence there are `_print` macros to handle the possibly comma separated values. Here we may just identify `_print` with `_unlock`.

With v1.2a the gathering of numbers happens directly inside `\csname ... \endcsname`. There is no more a ``locking'' macro.

```

57 \def\bnumexpr {\romannumeral0\bnumeval }%
58 \def\bnumeval {\expandafter\BNE_wrap\romannumeral0\BNE_eval }%
59 \def\BNE_eval {\expandafter\BNE_until_end_a\romannumeral-`0\BNE_getnext }%

63 \let\BNE_done\space
64 \def\thebnumexpr
65             {\romannumeral-`0\expandafter\BNE_unlock\romannumeral0\BNE_eval }%
66 \def\bnethe #1{\romannumeral-`0\expandafter\xint_gobble_iii\romannumeral-`0#1}%
67 \def\BNE_unlock {\expandafter\BNE_unlock_a\string }%
68 \def\BNE_unlock_a #1.={}%

```

9.6 \BNE_getnext

The `getnext` scans forward to find a number: after expansion of what comes next, an opening parenthesis signals a parenthesized sub-expression, a `!` with catcode 11 signals there was there a sub `\bnumexpr ... \relax` (now evaluated), a minus sign is treated as a prefix operator inheriting its precedence level from the previous operator, a plus sign is swallowed, a `\count` or `\dimen` will get fetched to `\number` (in case of a count variable, this provides a full locked number but `\count 0 1` for example is like `1231` if `\count 0`'s value is `123`); a digit triggers the number scanner. With v1.2a the gathering of digits happens directly inside `\csname .=... \endcsname`. Leading zeroes are trimmed directly. The flow then proceeds with `\BNE_getop` which looks for the next operator or possibly the end of the expression. Note: `\bnumexpr \relax` is illegal.

Extended in v1.2a to recognize `\ht`, etc...

```

69 \def\BNE_getnext #1%
70 {%
71     \expandafter\BNE_getnext_a\romannumeral-`0#1%

This is quite simplified here compared to `\xintexpr`, for various reasons: we have dropped the `\xintNewExpr` thing, and we can treat the `(` directly as we don't have to get back to check if we are in an `\xintexpr`, `\xintfloatexpr`, etc..

```

100 \def\BNE_gn_fork #1{%
101     \if#1+\xint_dothis \BNE_getnext\fi

105 }%

```

9.7 Parsing an integer

We gather a string of digits, plus and minus prefixes have already been swallowed. There might be some leading string of zeros which will have to be removed. In the full `\xintexpr` the situation is more involved as it has to recognize and accept decimal numbers, numbers in scientific notation, also hexadecimal numbers, function names, variable names...

```

106 \def\BNE_scan_number #1% this #1 has necessarily here catcode 12
107 {%
108     \ifnum \xint_c_ix<1#1 \else\expandafter\BNE_notadigit\fi

111 \def\BNE_notadigit\BNE_scan_nbr #1{\BNE:not_a_digit!\BNE_getnext }%

```

Scanning for a number. We gather it directly inside `csname`. earlier version did a chain of `romannumeral`. No limit on number of digits anymore from the maximal expansion depth. We only have to be careful about leading zeros.

If we hit against some catcode eleven `!`, this means there was a sub `\bnumexpr ..\relax`. We then apply tacit multiplication.

```

9.8 \BNE_getop

This finds the next infix operator or closing parenthesis or expression end. It then leaves in the token flow <precedence> <operator> <locked number>. The <precedence> stops expansion and ultimately gives back control to a `\BNE_until_<op>` command. The code here is derived from more involved context where the actual macro associated to

Contents

the operator may vary, depending if we are in `\xintexpr`, `\xintfloatexpr` or `\xintiiexpr`. Here things are simpler but I have kept the general scheme, thus the actual macro to be used for the `<operator>` is not decided immediately.

`v1.2a` adds a technique for allowing two-letters operators, for `//`, `/:` and `**`.

```

9.10 The arithmetic operators.

This is where the infix operators are mapped to actual macros. These macros must ``expand'' their arguments, and know how to handle then big integers having no leading zeros and at most a minus sign.

[v1.2a](#) adds `//` for truncated division, `/:` for modulo operations and `**` for powers (synonym to `^`).

[v1.2c](#) has `//` and `/:` per default associated to floored division.

9.13 The comma may separate expressions.

It suffices to treat the comma as a binary operator of precedence `i`. We insert a space after the comma. The current code in `\xintexpr` does not do it at this stage, but only later during the final unlocking, as there is anyhow need for some processing for final formatting and was considered to be as well the opportunity to insert the space. Here, let's do it immediately. These spaces are not an issue when `\bnumexpr` is identified as a sub-expression in `\xintexpr`, for example in: `\xinttheiiexpr lcm(\bnumexpr 175-12,12 23+34,56*31\relax)\relax` (this example requires package `xintgcd`).
