

# **expkv**

## an expandable $\langle \text{key} \rangle = \langle \text{value} \rangle$ implementation

Jonathan P. Spratte\*

2021-04-11 v1.7a

### Abstract

**expkv** provides a small interface for  $\langle \text{key} \rangle = \langle \text{value} \rangle$  parsing. The parsing macro is *fully expandable*, the  $\langle \text{code} \rangle$  of your keys might be not. **expkv** is *swift*, close to the fastest  $\langle \text{key} \rangle = \langle \text{value} \rangle$  implementation. However it is the fastest which copes with active commas and equal signs and doesn't strip braces accidentally.

# 1 Documentation

`expkv` provides an expandable  $\langle key \rangle = \langle value \rangle$  parser. The  $\langle key \rangle = \langle value \rangle$  pairs should be given as a comma separated list and the separator between a  $\langle key \rangle$  and the associated  $\langle value \rangle$  should be an equal sign. Both, the commas and the equal signs, might be of category 12 (other) or 13 (active). To support this is necessary as for example babel turns characters active for some languages, for instance the equal sign is turned active for Turkish.

`expkv` is usable as generic code or as a L<sup>A</sup>T<sub>E</sub>X package. To use it, just use one of:

```
\usepackage{expkv} % LaTeX  
\input expkv      % plainTeX
```

The L<sup>A</sup>T<sub>E</sub>X package doesn't do more than `expkv.tex`, except calling `\ProvidesPackage` and setting things up such that `expkv.tex` will use `\ProvidesFile`.

In the `expkv` family are other packages contained which provide additional functionality. Those packages currently are:

```
expkv|DEF a key-defining frontend for expkv using a <key>=<value> syntax  
expkv|CS define expandable <key>=<value> macros using expkv  
expkv|OPT parse package and class options with expkv
```

Note that while the package names are stylised with a vertical rule, their names are all lower case with a hyphen (*e.g.*, `expkv-def`).

A list of concise comparisons to other  $\langle key \rangle = \langle value \rangle$  packages is contained in subsection 1.7.

## 1.1 Setting up Keys

`expkv` provides a rather simple approach to setting up keys, similar to `keyval`. However there is an auxiliary package named `expkv|DEF` which provides a more sophisticated interface, similar to well established packages like `pgfkeys` or `l3keys`.

Keys in `expkv` (as in almost all other  $\langle key \rangle = \langle value \rangle$  implementations) belong to a *set* such that different sets can contain keys of the same name. Unlike many other implementations `expkv` doesn't provide means to set a default value, instead we have keys that take values and keys that don't (the latter are called `NoVal` keys by `expkv`), but both can have the same name (on the user level).

The following macros are available to define new keys. Those macros containing "def" in their name can be prefixed by anything allowed to prefix `\def` (but *don't* use `\outer`, keys defined with it won't ever be usable), prefixes allowed for `\let` can prefix those with "let" in their name, accordingly. Neither  $\langle set \rangle$  nor  $\langle key \rangle$  are allowed to be empty for new keys.  $\langle set \rangle$  will be used as is inside of `\csname ... \endcsname` and  $\langle key \rangle$  will get `\detokenized`.

---

```
\ekvdef{\{set\}}{\{key\}}{\{code\}}
```

Defines a  $\langle key \rangle$  taking a value in a  $\langle set \rangle$  to expand to  $\langle code \rangle$ . In  $\langle code \rangle$  you can use `#1` to refer to the given value.

*Example:* Define `text` in `foo` to store the value inside `\foo@text`:

```
\protected\long\ekvdef{foo}{text}{\def\foo@width{\#1}}
```

<u>\ekvdefNoVal</u>	<code>\ekvdefNoVal{\set}{\key}{\code}</code>
	Defines a no value taking <code>\key</code> in a <code>\set</code> to expand to <code>\code</code> . <i>Example:</i> Define bool in foo to set <code>\iffoo@bool</code> to true: <code>\protected\ekvdefNoVal{foo}{bool}{\foo@booltrue}</code>
<u>\ekvlet</u>	<code>\ekvlet{\set}{\key}{\cs}</code>
	Let the value taking <code>\key</code> in <code>\set</code> to <code>\cs</code> , there are no checks on <code>\cs</code> enforced. <i>Example:</i> Let cmd in foo do the same as <code>\foo@cmd</code> : <code>\ekvlet{foo}{cmd}{\foo@cmd}</code>
<u>\ekvletNoVal</u>	<code>\ekvletNoVal{\set}{\key}{\cs}</code>
	Let the no value taking <code>\key</code> in <code>\set</code> to <code>\cs</code> , it is not checked whether <code>\cs</code> exists or that it takes no parameter. <i>Example:</i> See above.
<u>\ekvletkv</u>	<code>\ekvletkv{\set}{\key}{\set2}{\key2}</code>
	Let the <code>\key</code> in <code>\set</code> to <code>\key2</code> in <code>\set2</code> , it is not checked whether that second key exists (but take a look at <code>\ekvifdefined</code> ). <i>Example:</i> Let B in bar be an alias for A in foo: <code>\ekvletkv{bar}{B}{foo}{A}</code>
<u>\ekvletkvNoVal</u>	<code>\ekvletkvNoVal{\set}{\key}{\set2}{\key2}</code>
	Let the <code>\key</code> in <code>\set</code> to <code>\key2</code> in <code>\set2</code> , it is not checked whether that second key exists (but take a look at <code>\ekvifdefinedNoVal</code> ). <i>Example:</i> See above.
<u>\ekvdefunknown</u>	<code>\ekvdefunknown{\set}{\code}</code>
	By default an error will be thrown if an unknown <code>\key</code> is encountered. With this macro you can define <code>\code</code> that will be executed for a given <code>\set</code> when an unknown <code>\key</code> with a <code>\value</code> was encountered instead of throwing an error. You can refer to the given <code>\value</code> with #1 and to the unknown <code>\key</code> 's name with #2 in <code>\code</code> . <sup>1</sup> <code>\ekvdefunknown</code> and <code>\ekvredirectunknown</code> are mutually exclusive, you can't use both. <i>Example:</i> Also search bar for undefined keys of set foo: <code>\long\ekvdefunknown{foo}{\ekvset{bar}{#2={#1}}}</code> This example differs from using <code>\ekvredirectunknown{foo}{bar}</code> (see below) in that also the unknown-key handler of the bar set will be triggered, error messages for undefined keys will look different, and this is slower than using <code>\ekvredirectunknown</code> .
<u>\ekvdefunknownNoVal</u>	<code>\ekvdefunknownNoVal{\set}{\code}</code>
	As already explained for <code>\ekvdefunknown</code> , <code>\expKV</code> would throw an error when encountering an unknown <code>\key</code> . With this you can instead let it execute <code>\code</code> if an unknown NoVal <code>\key</code> was encountered. You can refer to the given <code>\key</code> with #1 in <code>\code</code> . <code>\ekvdefunknownNoVal</code> and <code>\ekvredirectunknownNoVal</code> are mutually exclusive, you can't use both.

<sup>1</sup>That order is correct, this way the code is faster.

*Example:* Also search bar for undefined keys of set foo:  
`\ekvdefunknowNoVal{foo }{\ekvset{bar }{\#1}}`

---

#### \ekvredirectunknow

`\ekvredirectunknow{\set}{\set-list}`

This is a short cut to set up a special `\ekvdefunknow` for `\set` that will check each set in the comma separated `\set-list` for the unknown `\key`. You can't use prefixes (so no `\long` or `\protected`) with this macro, the resulting unknown-key handler will always be `\long`. The first set in the `\set-list` has highest priority. Once the `\key` is found the remaining sets are discarded, if the `\key` isn't found in any set an error will be thrown eventually. Note that the error messages are affected by the use of this macro, in particular, it isn't checked whether a `NoVal` key of the same name is defined in order to throw a `value forbidden` error. `\ekvdefunknow` and `\ekvredirectunknow` are mutually exclusive, you can't use both.

*Example:* For every key not defined in the set foo also search the sets bar and baz:  
`\ekvredirectunknow{foo }{bar, baz}`

---

#### \ekvredirectunknowNoVal

`\ekvredirectunknowNoVal{\set}{\set-list}`

This behaves just like `\ekvredirectunknow` and does the same but for the `NoVal` keys. Again no prefixes are supported. Note that the error messages are affected by the use of this macro, in particular, it isn't checked whether a normal key of the same name is defined in order to throw a `value forbidden` error. `\ekvdefunknowNoVal` and `\ekvredirectunknowNoVal` are mutually exclusive, you can't use both.

*Example:* See above.

## 1.2 Parsing Keys

---

#### \ekvset

`\ekvset{\set}{\key}=\value, ...}`

Splits `\key=\value` pairs on commas. From both `\key` and `\value` up to one space is stripped from both ends, if then only a braced group remains the braces are stripped as well. So `\ekvset{foo}{bar=baz}` and `\ekvset{foo}{ \ {bar}= \ {baz} }` will both do `\{foobarcode\}{baz}`, so you can hide commas, equal signs and spaces at the ends of either `\key` or `\value` by putting braces around them. If you omit the equal sign the code of the key created with the `NoVal` variants described in [subsection 1.1](#) will be executed. If `\key=\value` contains more than a single unhidden equal sign, it will be split at the first one and the others are considered part of the value. `\ekvset` should be nestable.

*Example:* Parse `key=arg, key` in the set foo:  
`\ekvset{foo }{\key=arg, key}`

---

#### \ekvsetSneaked

`\ekvsetSneaked{\set}{\sneak}{\key}=\value, ...}`

Just like `\ekvset`, this macro parses the `\key=\value` pairs within the given `\set`. But `\ekvsetSneaked` will behave as if `\ekvsneak` has been called with `\sneak` as its argument as the first action.

*Example:* Parse `key=arg, key` in the set foo with `\afterwards` sneaked out:  
`\ekvsetSneaked{foo }{\afterwards }{\key=arg, key}`

---

**\ekvsetdef**

```
\ekvsetdef{cs}{<set>}
```

With this function you can define a shorthand macro `{cs}` to parse keys of a specified `<set>`. It is always defined `\long`, but if you need to you can also prefix it with `\global`. The resulting macro is faster than but else equivalent to the idiomatic definition:

```
\long\def{cs}\#1{\ekvset{<set>}\#1}
```

*Example:* Define the macro `\foosetup` to parse keys in the set `foo` and use it to parse `key=arg, key`:

```
\ekvsetdef\foosetup{foo}
\foosetup{key=arg, key}
```

---

**\ekvsetSneakeddef**

```
\ekvsetSneakeddef{cs}{<set>}
```

Just like `\ekvsetdef` this defines a shorthand macro `{cs}`, but this macro will make it a shorthand for `\ekvsetSneaked`, meaning that `{cs}` will take two arguments, the first being stuff that should be given to `\ekvsneak` and the second the `<key>=<value>` list. The resulting macro is faster than but else equivalent to the idiomatic definition:

```
\long\def{cs}\#1\#2{\ekvsetSneaked{<set>}\#1\#2}
```

*Example:* Define the macro `\foothings` to parse keys in the set `foo` and accept a sneaked argument, then use it to parse `key=arg, key` and sneak `\afterwards`:

```
\ekvsetSneakeddef\foothings{foo}
\foothings{\afterwards}{key=arg, key}
```

---

**\ekvsetdefSneaked**

```
\ekvsetdefSneaked{cs}{<set>}{<sneaked>}
```

And this one behaves like `\ekvsetSneakeddef` but with a fixed `<sneaked>` argument. So the resulting macro is faster than but else equivalent to the idiomatic definition:

```
\long\def{cs}\#1{\ekvsetSneaked{<set>}{<sneaked>}\#1}
```

*Example:* Define the macro `\barthing` to parse keys in the set `bar` and always execute `\afterwards` afterwards, then use it to parse `key=arg, key`:

```
\ekvsetdefSneaked\barthing{bar}{\afterwards}
\barthing{key=arg, key}
```

---

**\ekvparses**

```
\ekvparses{<code1>}{<code2>}{<key>=<value>},...
```

This macro parses the `<key>=<value>` pairs and provides those list elements which are only keys as an argument to `<code1>`, and those which are a `<key>=<value>` pair to `<code2>` as two arguments. It is fully expandable as well and returns each element of the parsed list in `\unexpanded`, which has no effect outside of an `\expanded` or `\edef` context<sup>2</sup>. If you need control over the necessary steps of expansion you can use `\expanded` around it. You can use multiple tokens in `<code1>` and `<code2>` or just a single control sequence name. In both cases the found `<key>` and `<value>` are provided as a brace group following them.

`\ekvbreak`, `\ekvsneak`, and `\ekvchangeset` and their relatives don't work in `\ekvparses`. It is analogue to `expl3`'s \keyval_parse:Nn`, but not with the same parsing rules – `\keyval_parse:Nn` throws an error on multiple equal signs per `<key>=<value>` pair and on empty `<key>` names in a `<key>=<value>` pair, both of which `\ekvparses` doesn't deal with.

<sup>2</sup>This is a change in behaviour, previously (v0.3 and before) `\ekvparses` would expand in exactly two steps. This isn't always necessary, but makes the parsing considerably slower. If this is necessary for your application you can put an `\expanded` around it and will still be faster since you need only a single `\expandafter` this way.

*Example:*

```
\ekvparse{\handlekey{S}}{\handlekeyval{S}}{foo = bar, key, baz={zzz}}
```

would be equivalent to

```
\handlekeyval{S}{foo}{bar}\handlekey{S}{key}\handlekeyval{S}{baz}{zzz}
```

and afterwards `\handlekey` and `\handlekeyval` would have to further handle the `\key`. There are no macros like these two contained in `\expkv`, you have to set them up yourself if you want to use `\ekvparse` (of course the names might differ). If you need the results of `\ekvparse` as the argument for another macro, you should use `\expanded` as only then the input stream will contain the output above:

```
\expandafter\handle\expanded{\ekvparse{k\kv{foo = bar, key, baz={zzz}}}}
```

would expand to

```
\handle\kv{foo}{bar}\k{key}\kv{baz}{zzz}
```

### 1.3 Other Macros

`\expkv` provides some other macros which might be of interest.

---

```
\ekvVersion  
\ekvDate
```

---

These two macros store the version and date of the package.

---

```
\ekvifdefined  
\ekvifdefinedNoVal
```

---

```
\ekvifdefined{<set>}{<key>}{{<true>}}{{<false>}}  
\ekvifdefinedNoVal{<set>}{<key>}{{<true>}}{{<false>}}
```

These two macros test whether there is a `\key` in `\set`. It is false if either a hash table entry doesn't exist for that key or its meaning is `\relax`.

*Example:* Check whether the key `special` is already defined in set `foo`, if it isn't input a file that contains more key definitions:

```
\ekvifdefined{foo}{special}{}{\input{foo.morekeys.tex}}
```

---

```
\ekvifdefinedset
```

---

```
\ekvifdefinedset{<set>}{{<true>}}{{<false>}}
```

This macro tests whether `\set` is defined (which it is if at least one key was defined for it). If it is `<true>` will be run, else `<false>`.

*Example:* Check whether the set `VeRyUnLiKeLy` is already defined, if so throw an error, else do nothing:

```
\ekvifdefinedset{VeRyUnLiKeLy}  
  {\errmessage{VeRyUnLiKeLy already defined}}
```

---

```
\ekvbbreak  
\ekvbbreakPreSneak  
\ekvbbreakPostSneak
```

---

```
\ekvbbreak{<after>}
```

Gobbles the remainder of the current `\ekvset` macro and its argument list and reinserts `<after>`. So this can be used to break out of `\ekvset`. The first variant will also gobble anything that has been sneaked out using `\ekvsneak` or `\ekvsneakPre`, while `\ekvbbreakPreSneak` will put `<after>` before anything that has been smuggled and `\ekvbbreakPostSneak` will put `<after>` after the stuff that has been sneaked out.

*Example:* Define a key `abort` that will stop key parsing inside the set `foo` and execute `\foo@aborted`, or if it got a value `\foo@aborted@with`:

```
\ekvdefNoVal{foo }{{abort }{\ekvbreak{\foo@aborted }}}
\ekvdef{foo }{{abort }{\ekvbreak{\foo@aborted@with{\#1 }}}}
```

---

```
\ekvsneak{\ekvsneak{<after>}}
```

Puts `<after>` after the effects of `\ekvset`. The first variant will put `<after>` after any other tokens which might have been sneaked before, while `\ekvsneakPre` will put `<after>` before other smuggled stuff. This reads and reinserts the remainder of the current `\ekvset` macro and its argument list to do its job. After `\ekvset` has parsed the entire `<key>=<value>` list everything that has been `\ekvsneaked` will be left in the input stream. A small usage example is shown in [subsubsection 1.4.3](#).

*Example:* Define a key `secret` in the set `foo` that will sneak out a macro `\foo@secretly@sneaked`:

```
\ekvdefNoVal{foo }{{secret }{\ekvsneak{\foo@secretly@sneaked }}}
```

---

```
\ekvchangeset{\ekvchangeset{<new-set>}}
```

Replaces the current set with `<new-set>`, so for the rest of the current `\ekvset` call, that call behaves as if it was called with `\ekvset{<new-set>}`. It is comparable to using `<key>/ . cd` in pgfkeys.

*Example:* Define a key `cd` in set `foo` that will change to another set as specified in the value, if the set is undefined it'll stop the parsing and throw an error as defined in the macro `\foo@cd@error`:

```
\ekvdef{foo }{{cd }
  {\ekvifdefinedset{\#1}{\ekvchangeset{\#1}}{\ekvbreak{\foo@cd@error }}}}
```

---

```
\ekv@name
\ekv@name@set
\ekv@name@key
```

The names of the macros that correspond to a key in a set are build with these macros. The name is built from two blocks, one that is formatting the `<set>` name (`\ekv@name@set`) and one for formatting the `<key>` name (`\ekv@name@key`). To get the actual name the argument to `\ekv@name@key` must be `\detokenized`. Both blocks are put together (with the necessary `\detokenize`) by `\ekv@name`. For `NoVal` keys an additional `N` gets appended irrespective of these macros' definition, so their name is `\ekv@name{<set>}{<key>}N`.

You can use these macros to implement additional functionality or access key macros outside of `expKV`, but *don't* change them! `expKV` relies on their exact definitions internally.

*Example:* Execute the callback of the `NoVal` key `key` in set `foo`:

```
\csname\ekv@name{foo }{key }\endcsname
```

## 1.4 Examples

### 1.4.1 Standard Use-Case

Say we have a macro for which we want to create a `<key>=<value>` interface. The macro has a parameter, which is stored in the dimension `\ourdim` having a default value from its initialisation. Now we want to be able to change that dimension with the `width` key to some specified value. For that we'd do

```
\newdimen\ourdim
\ourdim=150pt
\protected\ekvdef{our}{width}{\ourdim=#1\relax}
```

as you can see, we use the set `our` here. We want the key to behave different if no value is specified. In that case the key should not use its initial value, but be smart and determine the available space from `\hsize`, so we also define

```
\protected\ekvdefNoVal{our}{width}{\ourdim=.9\hsize}
```

Now we set up our macro to use this  $\langle \text{key} \rangle = \langle \text{value} \rangle$  interface

```
\protected\def\ourmacro#1{\begingroup\ekvset{our}{#1}\the\ourdim\endgroup}
```

Finally we can use our macro like in the following

<code>\ourmacro{} \par</code>	150.opt
<code>\ourmacro{width} \par</code>	192.85382pt
<code>\ourmacro{width=5pt} \par</code>	5.opt

**The same keys using `expkv|DEF`** Using `expkv|DEF` we can set up the equivalent key using a  $\langle \text{key} \rangle = \langle \text{value} \rangle$  interface, after the following we could use `\ourmacro` in the same way as above. `expkv|DEF` will allocate and initialise `\ourdim` and define the `width` key `\protected` for us, so the result will be exactly the same – with the exception that the default will use `\ourdim=.9\hsize\relax` instead.

```
\input expkv-def % or \usepackage{expkv-def}
\ekvdefinekeys{our}
{
    dimen width = \ourdim,
    qdefault width = .9\hsize,
    initial width = 150pt
}
```

#### 1.4.2 A Macro to Draw Rules

Another small example could be a  $\langle \text{key} \rangle = \langle \text{value} \rangle$  driven `\rule` alternative, because I keep forgetting the correct order of its arguments. First we define the keys (and initialize the used macros to store the keys):

```
\makeatletter
\newcommand*\myrule@ht{1ex}
\newcommand*\myrule@wd{0.1em}
\newcommand*\myrule@raise{\z@}
\protected\ekvdef{myrule}{ht}{\def\myrule@ht{\#1}}
\protected\ekvdef{myrule}{wd}{\def\myrule@wd{\#1}}
\protected\ekvdef{myrule}{raise}{\def\myrule@raise{\#1}}
```

Then we define a macro to change the defaults outside of `\myrule` and `\myrule` itself:

```
\ekvsetdef\myruleset{myrule}
\newcommand*\myrule[1][] {\begingroup\myruleset{\#1}\myrule@out\endgroup}
```

And finally the output:

```
\newcommand*\myrule@out{\rule[\myrule@raise]\myrule@wd\myrule@ht}
\makeatother
```

And we can use it:

```
a\myrule\par
a\myrule[ht=2ex, raise=-.5ex]\par      ai
\myruleset{wd=5pt}                      a|
a\myrule                                a■
```

#### 1.4.3 An Expandable $\langle key \rangle = \langle value \rangle$ Macro Using \ekvsneak

Let's set up an expandable macro, that uses a  $\langle key \rangle = \langle value \rangle$  interface. The problems we'll face for this are:

1. ignoring duplicate keys
2. default values for keys which weren't used
3. providing the values as the correct argument to a macro (ordered)

First we need to decide which  $\langle key \rangle = \langle value \rangle$  parsing macro we want to do this with, \ekvset or \ekvpars. For this example we also want to show the usage of \ekvsneak, hence we'll choose \ekvset. And we'll have to use \ekvset such that it builds a parsable list for our macro internals. To gain back control after \ekvset is done we have to put an internal of our macro at the start of that list, so we use an internal key that uses \ekvsneakPre after any user input.

To ignore duplicates will be easy if the value of the key used last will be put first in the list, so the following will use \ekvsneakPre for the user-level keys. If we wanted some key for which the first usage should be the binding one we would use \ekvsneak instead for that key.

Providing default values can be done in different ways, we'll use a simple approach in which we'll just put the outcome of our keys if they were used with default values before the parsing list terminator.

Ordering the keys can be done simply by searching for a specific token for each argument which acts like a flag, so our sneaked out values will include specific tokens acting as markers.

Now that we have answers for our technical problems, we have to decide what our example macro should do. How about we define a macro that calculates the sine of a number and rounds that to a specified precision? As a small extra this macro should understand input in radian and degree and the used trigonometric function should be selectable as well. For the hard part of this task (expandably evaluating trigonometric functions) we'll use the xfp package.

First we set up our keys according to our earlier considerations and set up the user facing macro \sine. The end marker of the parsing list will be a \sine@stop token, which we don't need to define and we put our defaults right before it.

```
\RequirePackage{xfp}
\makeatletter
\ekvdef{expex}{f}{\ekvsneakPre{\f{\#1}}}
\ekvdef{expex}{round}{\ekvsneakPre{\rnd{\#1}}}
\ekvdefNoVal{expex}{degree}{\ekvsneakPre{\deg{d}}}
\ekvdefNoVal{expex}{radian}{\ekvsneakPre{\deg{}}}
```

```
\ekvdefNoVal{expex}{internal}{\ekvsneakPre{\sine@rnd}}
\newcommand*\sine[2]
  {\ekvset{expex}{#1,internal}\rnd{3}\deg{d}\f{sin}\sine@stop{#2}}
```

For the sake of simplicity we defined the macro `\sine` with two mandatory arguments, the first being the  $\langle key \rangle = \langle value \rangle$  list, the second the argument to the trigonometric function. We could've used `xparse`'s facilities here to define an expandable macro which takes an optional argument instead.

Now we need to define some internal macros to extract the value of each key's last usage (remember that this will be the group after the first special flag-token). For that we use one delimited macro per key.

```
\def\sine@rnd#1\rnd#2#3\sine@stop{\sine@deg#1#3\sine@stop{#2}}
\def\sine@deg#1\deg#2#3\sine@stop{\sine@f#1#3\sine@stop{#2}}
\def\sine@f#1\f#2#3\sine@stop{\sine@final{#2}}
```

After the macros `\sine@rnd`, `\sine@deg`, and `\sine@f` the macro `\sine@final` will see `\sine@final{<f>}{<degree/radian>}{<round>}{<num>}`. Now `\sine@final` has to expandably deal with those arguments such that the `\fpeval` macro of `xfp` gets the correct input. Luckily this is pretty straight forward in this example. In `\fpeval` the trigonometric functions have names such as `sin` or `cos` and the degree taking variants `sind` or `cosd`. And since the `degree` key puts a `d` in `#2` and the `radian` key leaves `#2` empty all we have to do to get the correct function name is stick the two together.

```
\newcommand*\sine@final[4]{\fpeval{round(#1#2(#4),#3)}}
\makeatother
```

Let's test our macro:

<code>\sine{}{60}\par</code>	0.866
<code>\sine{round=10}{60}\par</code>	0.8660254038
<code>\sine{f=cos,radian}{pi}\par</code>	-1
<code>\edef\myval{\sine{f=tan}{1}}\texttt{\meaning\myval}</code>	macro:->0.017

**The same macro using `expkvcs`** Using `expkvcs` we can set up something equivalent with a bit less code. The implementation chosen in `expkvcs` is more efficient than the example above and way easier to code for the user.

```
\makeatletter
\ekvcSplitAndForward\sine\sine@
{
  f=sin,
  unit=d,
  round=3,
}
\ekvcSecondaryKeys\sine
{
  nmeta degree={unit=d},
  nmeta radian={unit={}},
}
\newcommand*\sine@[4]{\fpeval{round(#1#2(#4),#3)}}
\makeatother
```

The resulting macro will behave just like the one previously defined, but will have an additional unit key, since in `expkv`s every argument must have a value taking key which defines it.

## 1.5 Error Messages

`expkv` should only send messages in case of errors, there are no warnings and no info messages. In this subsection those errors are listed.

### 1.5.1 Load Time

`expkv.tex` checks whether  $\varepsilon$ - $\text{TeX}$  is available. If it isn't, an error will be thrown using `\errmessage`:

```
! expkv Error: e-TeX required.
```

### 1.5.2 Defining Keys

If you get any error from `expkv` while you're trying to define a key, the definition will be aborted and gobbled.

If you try to define a key with an empty set name you'll get:

```
! expkv Error: empty set name not allowed.
```

Similarly, if you try to define a key with an empty key name:

```
! expkv Error: empty key name not allowed.
```

Both of these messages are done in a way that doesn't throw additional errors due to `\global`, `\long`, etc., not being used correctly if you prefixed one of the defining macros.

### 1.5.3 Using Keys

This subsubsection contains the errors thrown during `\ekvset`. The errors are thrown in an expandable manner by providing an undefined macro. In the following messages `<key>` gets replaced with the problematic key's name, and `<set>` with the corresponding set. If any errors during `<key>=<value>` handling are encountered, the entry in the comma separated list will be omitted after the error is thrown and the next `<key>=<value>` pair will be parsed.

If you're using an undefined key you'll get:

```
! Undefined control sequence.
<argument> \! expkv Error:
unknown key ('<key>', set '<set>').
```

If you're using a key for which only a normal version and no `NoVal` version is defined, but don't provide a value, you'll get:

```
! Undefined control sequence.
<argument> \! expkv Error:
value required ('<key>', set '<set>').
```

If you're using a key for which only a `NoVal` version and no normal version is defined, but provide a value, you'll get:

```

! Undefined control sequence.
<argument> \! expkv Error:
                                value forbidden ('<key>', set '<set>').

```

If you're using an undefined key in a set for which `\ekvredirectunknown` was used, and the key isn't found in any of the other sets as well, you'll get:

```

! Undefined control sequence.
<argument> \! expkv Error:
                                no key '<key>' in sets {<set1>} {<set2>} ...

```

If you're using an undefined `NoVal` key in a set for which `\ekvredirectunknownNoVal` was used, and the key isn't found in any of the other sets as well, you'll get:

```

! Undefined control sequence.
<argument> \! expkv Error:
                                no NoVal key '<key>' in sets {<set1>} ...

```

If you're using a set for which you never executed one of the defining macros from [subsection 1.1](#) you'll get a low level TeX error, as that isn't actively tested by the parser (and hence will lead to undefined behaviour and not be gracefully ignored). The error will look like

```

! Missing \endcsname inserted.
<to be read again>
                                \! expkv Error: Set '<set>' undefined.

```

## 1.6 Bugs

Just like `keyval`, `expkv` is bug free. But if you find `bugshidden` features<sup>3</sup> you can tell me about them either via mail (see the first page) or directly on GitHub if you have an account there: [https://github.com/Skillmon/tex\\_expkv](https://github.com/Skillmon/tex_expkv)

## 1.7 Comparisons

This subsection makes some basic comparison between `expkv` and other `<key>=<value>` packages. The comparisons are really concise, regarding speed, feature range (without listing the features of each package), and bugs and misfeatures.

Comparisons of speed are done with a very simple test key and the help of the `\l3benchmark` package. The key and its usage should be equivalent to

```

\protected\ekvdef{test}{{height}}{\def\myheight{\#1}}
\ekvsetdef\expkvttest{test}
\expkvttest{height = 6}

```

and only the usage of the key, not its definition, is benchmarked. For the impatient, the essence of these comparisons regarding speed and buggy behaviour is contained in [Table 1](#).

As far as I know `expkv` is the only fully expandable `<key>=<value>` parser. I tried to compare `expkv` to every `<key>=<value>` package listed on [CTAN](#), however, one might notice that some of those are missing from this list. That's because I didn't get the others

---

<sup>3</sup>Thanks, David!

to work due to bugs, or because they just provide wrappers around other packages in this list.

In this subsection is no benchmark of `\ekvparse` and `\keyval_parse`:NNn contained, as most other packages don't provide equivalent features to my knowledge. `\ekvparse` is slightly faster than `\ekvset`, but keep in mind that it does less. The same is true for `\keyval_parse`:NNn compared to `\keys_set`:nn of `expl3` (where the difference is much bigger). Comparing just the two, `\ekvparse` is a tad faster than `\keyval_parse`:NNn because of the two tests (for empty key names and only a single equal sign) which are omitted.

`keyval` is about 30 % to 40 % faster and has a comparable feature set (actually a bit smaller since `expkv` supports unknown-key handlers and redirection to other sets) just a slightly different way how it handles keys without values. That might be considered a drawback, as it limits the versatility, but also as an advantage, as it might reduce doubled code. Keep in mind that as soon as someone loads `xkeyval` the performance of `keyval` gets replaced by `xkeyval`'s.

Also `keyval` has a bug, which unfortunately can't really be resolved without breaking backwards compatibility for *many* documents, namely it strips braces from the argument before stripping spaces if the argument isn't surrounded by spaces, also it might strip more than one set of braces. Hence all of the following are equivalent in their outcome, though the last two lines should result in something different than the first two:

```
\setkeys{foo}{bar=baz}
\setkeys{foo}{bar= {baz}}
\setkeys{foo}{bar={ baz}} % should be ' baz'
\setkeys{foo}{bar={{baz}}} % should be '{baz}'
```

`xkeyval` is roughly twenty times slower, but it provides more functionality, e.g., it has choice keys, boolean keys, and so on. It contains the same bug as `keyval` as it has to be compatible with it by design (it replaces `keyval`'s frontend), but also adds even more cases in which braces are stripped that shouldn't be stripped, worsening the situation.

`ltxkeys` is no longer compatible with the L<sup>A</sup>T<sub>E</sub>X kernel starting with the release 2020-10-01. It is over 380 times slower – which is funny, because it aims to be “[...] faster [...] than these earlier packages [referring to `keyval` and `xkeyval`].” It needs more time to parse zero keys than five of the packages in this comparison need to parse 100 keys. Since it aims to have a bigger feature set than `xkeyval`, it most definitely also has a bigger feature set than `expkv`. Also, it can't parse `\long` input, so as soon as your values contain a `\par`, it'll throw errors. Furthermore, `ltxkeys` doesn't strip outer braces at all by design, which, imho, is a weird design choice. In addition `ltxkeys` loads `catoptions` which is known to introduce bugs (e.g., see <https://tex.stackexchange.com/questions/461783>). Because it is no longer compatible with the kernel, I stop benchmarking it (so the numbers listed here and in [Table 1](#) regarding `ltxkeys` were last updated on 2020-10-05).

`l3keys` is around four and a half times slower, but has an, imho, great interface to define keys. It strips *all* outer spaces, even if somehow multiple spaces ended up on either end. It offers more features, but is pretty much bound to `expl3` code. Whether that's a drawback is up to you.

`pgfkeys` is around 2.7 times slower for one key if one uses the `/⟨path⟩/.cd` syntax and almost 20 % slower if one uses `\pgfqkeys`, but has an *enormous* feature set. To get the best performance `\pgfqkeys` was used in the benchmark. This reduces the overhead for setting the base directory of the benchmark keys by about 43 ops (so both  $p_0$  and  $T_0$  would be about 43 ops bigger if `\pgfkeys{⟨path⟩/.cd,⟨keys⟩}` was used instead). It has the same or a very similar bug `keyval` has. The brace bug (and also the category fragility) can be fixed by `pgfkeyx`, but this package was last updated in 2012 and it slows down `\pgfkeys` by factor 8. Also `pgfkeyx` is no longer compatible with versions of `pgfkeys` newer than 2020-05-25.

`kvsetkeys` with `kvdefinekeys` is about 4.4 times slower, but it works even if commas and equals have category codes different from 12 (just as some other packages in this list). Else the features of the keys are equal to those of `keyval`, the parser has more features, though.

`options` is 1.7 times slower for only a single value. It has a much bigger feature set. Unfortunately it also suffers from the premature unbracing bug `keyval` has.

`simplekv` is hard to compare because I don't speak French (so I don't understand the documentation). There was an update released on 2020-04-27 which greatly improved the package's performance and adds functionality so that it can be used more like most of the other `⟨key⟩=⟨value⟩` packages. It has problems with stripping braces and spaces in a hard to predict manner just like `keyval`. Also, while it tries to be robust against category code changes of commas and equal signs, the used mechanism fails if the `⟨key⟩=⟨value⟩` list already got tokenised. Regarding unknown keys it got a very interesting behaviour. It doesn't throw an error, but stores the `⟨value⟩` in a new entry accessible with `\useKV`. Also if you omit `⟨value⟩` it stores `true` for that `⟨key⟩`. For up to three keys, `expKV` is a bit faster, for more keys `simplekv` takes the lead.

`YAX` is over twenty times slower. It has a pretty strange syntax for the TeX-world, imho, and again a direct equivalent is hard to define (don't understand me wrong, I don't say I don't like the syntax, it's just atypical). It has the premature unbracing bug, too. Also somehow loading `YAX` broke options for me. The tested definition was:

```
\usepackage{yax}
\defactiveparameter yax {\storevalue\myheight yax:height } % key setup
\setparameterlist{yax}{ height = 6 } % benchmarked
```

<http://www.latex-project.org/lppl.txt>

This work is “maintained” (as per LPPL maintenance status) by  
Jonathan P. Spratte.

Table 1: Comparison of  $\langle \text{key} \rangle = \langle \text{value} \rangle$  packages. The packages are ordered from fastest to slowest for one  $\langle \text{key} \rangle = \langle \text{value} \rangle$  pair. Benchmarking was done using `l3benchmark` and the scripts in the `Benchmarks` folder of the [git repository](#). The columns  $p_i$  are the polynomial coefficients of a linear fit to the run-time,  $p_0$  can be interpreted as the overhead for initialisation and  $p_1$  the cost per key. The  $T_0$  column is the actual mean ops needed for an empty list argument, as the linear fit doesn't match that point well in general. The column "BB" lists whether the parsing is affected by some sort of brace bug, "CF" stands for category code fragile and lists whether the parsing breaks with active commas or equal signs.

Package	$p_1$	$p_0$	$T_0$	BB	CF	Date
keyval	13.7	1.5	7.3	yes	yes	2014-10-28
<b>expkv</b>	19.7	2.2	6.6	no	no	2020-10-10
simplekv	18.3	7.0	17.7	yes	yes	2020-04-27
pgfkeys	24.3	1.7	10.7	yes	yes	2020-09-05
options	23.6	15.6	20.8	yes	yes	2015-03-01
kvsetkeys	*	*	40.3	no	no	2019-12-15
l3keys	71.3	33.1	31.6	no	no	2020-09-24
xkeyval	253.6	202.2	168.3	yes	yes	2014-12-03
Y <sup>A</sup> X	421.9	157.0	114.7	yes	yes	2010-01-22
ltxkeys	3400.1	4738.0	5368.0	no	no	2012-11-17

\*For kvsetkeys the linear model used for the other packages is a poor fit, kvsetkeys seems to have approximately quadratic run-time, the coefficients of the second degree polynomial fit are  $p_2 = 8.2$ ,  $p_1 = 44.9$ , and  $p_0 = 60.8$ . Of course the other packages might not really have linear run-time, but at least from 1 to 20 keys the fits don't seem too bad. If one extrapolates the fits for 100  $\langle \text{key} \rangle = \langle \text{value} \rangle$  pairs one finds that most of them match pretty well, the exception being ltxkeys, which behaves quadratic as well with  $p_2 = 23.5$ ,  $p_1 = 2906.6$ , and  $p_0 = 6547.5$ .

## 2 Implementation

### 2.1 The L<sup>A</sup>T<sub>E</sub>X Package

First we set up the L<sup>A</sup>T<sub>E</sub>X package. That one doesn't really do much except \inputting the generic code and identifying itself as a package.

```
1 \def\ekv@tmp
2   {%
3     \ProvidesFile{expkv.tex}%
4     [\ekvDate\space v\ekvVersion\space an expandable key=val implementation]%
5   }
6 \input{expkv.tex}
7 \ProvidesPackage{expkv}%
8   [\ekvDate\space v\ekvVersion\space an expandable key=val implementation]
```

### 2.2 The Generic Code

The rest of this implementation will be the generic code.

We make sure that it's only input once:

```
9 \expandafter\ifx\csname ekvVersion\endcsname\relax
10 \else
11   \expandafter\endinput
12 \fi
13 \begingroup\expandafter\expandafter\expandafter\endgroup
14 \expandafter\ifx\csname numexpr\endcsname\relax
15   \errmessage{expkv requires e-TeX}
16 \expandafter\endinput
17 \fi
```

Check whether e-TeX is available – expkv requires e-TeX.

\ekvVersion We're on our first input, so lets store the version and date in a macro.

```
18 \def\ekvVersion{1.7a}
19 \def\ekvDate{2021-04-11}
```

(End definition for \ekvVersion and \ekvDate. These functions are documented on page 6.)

If the L<sup>A</sup>T<sub>E</sub>X format is loaded we want to be a good file and report back who we are, for this the package will have defined \ekv@tmp to use \ProvidesFile, else this will expand to a \relax and do no harm.

```
20 \csname ekv@tmp\endcsname
```

Store the category code of @ to later be able to reset it and change it to 11 for now.

```
21 \expandafter\chardef\csname ekv@tmp\endcsname=\catcode`@
22 \catcode`@=11
```

\ekv@tmp might later be reused to gobble any prefixes which might be provided to \ekvdef and similar in case the names are invalid, we just temporarily use it here as means to store the current category code of @ to restore it at the end of the file, we never care for the actual definition of it.

\ekv@if@lastnamedcs If the primitive \lastnamedcs is available, we can be a bit faster than without it. So we test for this and save the test's result in this macro.

```

23  \begingroup
24  \edef\ekv@tmpa{\string \lastnamedcs}
25  \edef\ekv@tmpb{\meaning\lastnamedcs}
26  \ifx\ekv@tmpa\ekv@tmpb
27  \def\ekv@if@lastnamedcs{\long\def\ekv@if@lastnamedcs##1##2{##1}}
28  \else
29  \def\ekv@if@lastnamedcs{\long\def\ekv@if@lastnamedcs##1##2{##2}}
30  \fi
31  \expandafter
32  \endgroup
33  \ekv@if@lastnamedcs

```

(End definition for \ekv@if@lastnamedcs.)

\ekv@empty Sometimes we have to introduce a token to prevent accidental brace stripping. This token would then need to be removed by \gobble or similar. Instead we can use \ekv@empty which will just expand to nothing, that is faster than gobbling an argument.

```
34  \def\ekv@empty{}
```

(End definition for \ekv@empty.)

Since branching tests are often more versatile than \if... \else... \fi constructs, we define helpers that are branching pretty fast. Also here are some other utility functions that just grab some tokens. The ones that are also contained in LATEX don't use the ekv prefix. Not all of the ones defined here are really needed by explV but are provided because packages like explV|DEF or explV|OPT need them (and I don't want to define them in each package which might need them).

```

35  \long\def@gobble#1{}
36  \long\def@firstofone#1{#1}
37  \long\def@firstoftwo#1#2{#1}
38  \long\def@secondoftwo#1#2{#2}
39  \long\def\ekv@fi@gobble\fi@firstofone#1{\fi}
40  \long\def\ekv@fi@firstofone\fi@gobble#1{\fi#1}
41  \long\def\ekv@fi@firstoftwo\fi@secondoftwo#1#2{\fi#1}
42  \long\def\ekv@fi@secondoftwo\fi@firstoftwo#1#2{\fi#2}
43  \def\ekv@gobble@mark\ekv@mark{}
44  \long\def\ekv@gobbleto@stop#1\ekv@stop{}
45  \long\def\ekv@gobble@from@mark@to@stop\ekv@mark#1\ekv@stop{}

```

(End definition for @gobble and others.)

As you can see \ekv@gobbleto@stop uses a special marker \ekv@stop. The package will use three such markers, the one you've seen already, \ekv@mark and \ekv@nil. Contrarily to how for instance expl3 does things, we don't define them, as we don't need them to have an actual meaning. This has the advantage that if they somehow get expanded – which should never happen if things work out – they'll throw an error directly.

We can test for a lot of things building on an if-empty test, so lets define a really fast one. Since some tests might have reversed logic (true if something is not empty) we also set up macros for the reversed branches.

```
46  \long\def\ekv@ifempty#1%
```

```

\ekv@ifempty
\ekv@ifempty@
\ekv@ifempty@true
\ekv@ifempty@false
\ekv@ifempty@true@F
\ekv@ifempty@true@F@gobble
\ekv@ifempty@true@F@gobbletwo

```

```

47  {%
48      \ekv@ifempty@{\ekv@ifempty@A#1\ekv@ifempty@B\ekv@ifempty@true
49          \ekv@ifempty@A\ekv@ifempty@B\@secondoftwo
50      }
51  \long\def\ekv@ifempty@#1{\ekv@ifempty@A\ekv@ifempty@B{}}
52  \long\def\ekv@ifempty@true{\ekv@ifempty@A\ekv@ifempty@B\@secondoftwo#1#2{#1}}
53  \long\def\ekv@ifempty@false{\ekv@ifempty@A\ekv@ifempty@B\@firstoftwo#1#2{#2}}
54  \long\def\ekv@ifempty@true@F{\ekv@ifempty@A\ekv@ifempty@B\@firstofone#1{}}
55  \long\def\ekv@ifempty@true@F@gobble{\ekv@ifempty@A\ekv@ifempty@B\@firstofone#1#2%}
56      {}
57  \long\def\ekv@ifempty@true@F@gobbletwo
58      \ekv@ifempty@A\ekv@ifempty@B\@firstofone#1#2#3%
59  {}
```

(End definition for `\ekv@ifempty` and others.)

`\ekv@ifblank`  
`\ekv@ifblank@`

The obvious test that can be based on an if-empty is if-blank, meaning a test checking whether the argument is empty or consists only of spaces. Our version here will be tweaked a bit, as we want to check this, but with one leading `\ekv@mark` token that is to be ignored. The wrapper `\ekv@ifblank` will not be used by `expKV` for speed reasons but `expKV|OPT` uses it.

```

60  \long\def\ekv@ifblank#1%
61  {%
62      \ekv@ifblank@#1\ekv@nil\ekv@ifempty@B\ekv@ifempty@true
63          \ekv@ifempty@A\ekv@ifempty@B\@secondoftwo
64      }
65  \long\def\ekv@ifblank@\ekv@mark#1{\ekv@ifempty@\ekv@ifempty@A}
```

(End definition for `\ekv@ifblank` and `\ekv@ifblank@`)

`\ekv@ifdefined`

We'll need to check whether something is defined quite frequently, so why not define a macro that does this. The following test is expandable and pretty fast. The version with `\lastnamedcs` is the fastest version to test for an undefined macro I know of (that considers both undefined macros and those with the meaning `\relax`).

```

66  \ekv@if@lastnamedcs
67  {%
68      \def\ekv@ifdefined#1{\ifcsname#1\endcsname\ekv@ifdef@\fi\@secondoftwo}
69      \def\ekv@ifdef@\fi\@secondoftwo
70      {%
71          \fi
72          \expandafter\ifx\lastnamedcs\relax
73              \ekv@fi@secondoftwo
74          \fi
75          \@firstoftwo
76      }
77  }
78  {%
79      \def\ekv@ifdefined#1%
80      {%
81          \ifcsname#1\endcsname\ekv@ifdef@\fi\ekv@ifdef@false#1\endcsname\relax
82              \ekv@fi@secondoftwo
83          \fi
84          \@firstoftwo
85      }
86 }
```

```

86      \def\ekv@ifdef@#1\fi\ekv@ifdef@false{\fi\expandafter\ifx\csname}
87      \long\def\ekv@ifdef@false
88          #1\endcsname\relax\ekv@fi@secondoftwo\fi\@firstoftwo#2#3%
89          {#3}
90      }

```

(End definition for `\ekv@ifdefined`.)

`\ekv@strip`  
`\ekv@strip@a`  
`\ekv@strip@b`  
`\ekv@strip@c`

We borrow some ideas of `expl3`'s `l3tl` to strip spaces from keys and values. This `\ekv@strip` also strips one level of outer braces *after* stripping spaces, so an input of `{abc}` becomes `abc` after stripping. It should be used with `#1` prefixed by `\ekv@mark`. Also this implementation at most strips *one* space from both sides (which should be fine most of the time, since TeX reads consecutive spaces as a single one during tokenisation).

```

91  \def\ekv@strip#1%
92  {%
93      \long\def\ekv@strip##1%
94      {%
95          \ekv@strip@a
96          ##1\ekv@nil
97          \ekv@mark#1%
98          #1\ekv@nil
99      }%
100     \long\def\ekv@strip@a##1\ekv@mark#1{\ekv@strip@b##1\ekv@mark}%
101   }
102 \ekv@strip{ }
103 \long\def\ekv@strip@b#1 \ekv@nil{\ekv@strip@c#1\ekv@nil}
104 \long\def\ekv@strip@c\ekv@mark#1\ekv@nil\ekv@mark#2\ekv@nil#3{#3{#1}}

```

(End definition for `\ekv@strip` and others.)

`\ekv@exparg`  
`\ekv@exparg@`  
`\ekv@expargtwice`  
`\ekv@expargtwice@`  
`\ekv@zero`

To reduce some code doublets while gaining some speed (and also as convenience for other packages in the family), it is often useful to expand the first token in a definition once. Let's define a wrapper for this.

Also, to end a `\romannumeral` expansion, we want to use `\z@`, which is contained in both plain TeX and L<sup>A</sup>T<sub>E</sub>X, but we use a private name for it to make it easier to spot and hence easier to manage.

```

105 \let\ekv@zero\z@
106 \long\def\ekv@exparg#1#2{\expandafter\ekv@exparg@\expandafter{#2}{#1}}
107 \long\def\ekv@exparg@#1#2{#2{#1}}%

109 \def\ekv@expargtwice@{\expandafter\ekv@exparg@\expandafter}

```

(End definition for `\ekv@exparg` and others.)

`\ekv@csv@loop`  
`\ekv@csv@loop@do`  
`\ekv@csv@loop@end`

This is just a very simple loop over a list of comma separated values, leaving each element as the argument to a specified function inside of `\unravel`. It should be used as `\ekv@csv@loop{<function>} \ekv@mark<csv-list>, \ekv@stop, .` We use some `\expandafter` chain to preexpand `\ekv@strip` here.

```

110 \ekv@exparg{\long\def\ekv@csv@loop#1#2,}{%
111 {%
112     \expandafter
113     \ekv@gobble@from@mark@to@stop
114     \expandafter#\expandafter2\expandafter\expandafter\ekv@csv@loop@end\expandafter
115     \ekv@stop

```

```

116      \ekv@strip{\#2}{\ekv@csv@loop@do{\#1}}%
117      \ekv@csv@loop{\#1}\ekv@mark
118  }
119 \long\def\ekv@csv@loop@do#1#2{\unexpanded{\#1{\#2}}}
120 \long\expandafter\def\expandafter\ekv@csv@loop@end
121     \expandafter\ekv@stop
122     \ekv@strip{\#1}#2%
123     \ekv@csv@loop#3\ekv@mark
124 {}}

```

(End definition for `\ekv@csv@loop`, `\ekv@csv@loop@do`, and `\ekv@csv@loop@end`.)

`\ekv@name` The keys will all follow the same naming scheme, so we define it here.

```

125 \def\ekv@name@set#1{\ekv#1{}}
126 \def\ekv@name@key#1{\#1}
127 \edef\ekv@name
128   {%
129     \unexpanded\expandafter{\ekv@name@set{\#1}}%
130     \unexpanded\expandafter{\ekv@name@key{\detokenize{\#2}}}%
131   }
132 \ekv@exparg{\def\ekv@name#1#2}{\ekv@name}

```

(End definition for `\ekv@name`, `\ekv@name@set`, and `\ekv@name@key`. These functions are documented on page 7.)

`\ekv@undefined@set` We can misuse the macro name we use to expandably store the set-name in a single token – since this increases performance drastically, especially for long set-names – to throw a more meaningful error message in case a set isn't defined. The name of `\ekv@undefined@set` is a little bit misleading, as it is called in either case inside of `\csname`, but the result will be a control sequence with meaning `\relax` if the set is undefined, hence will break the `\csname` building the key-macro which will throw the error message.

```
133 \def\ekv@undefined@set#1{! expkv Error: Set '#1' undefined.}
```

(End definition for `\ekv@undefined@set`.)

`\ekv@checkvalid` We place some restrictions on the allowed names, though, namely sets and keys are not allowed to be empty – blanks are fine (meaning set- or key-names consisting of spaces). The `\def\ekv@tmp` gobbles any TeX prefixes which would otherwise throw errors. This will, however, break the package if an `\outer` has been gobbled this way. I consider that good, because keys shouldn't be defined `\outer` anyways.

```

134 \edef\ekv@checkvalid
135   {%
136     \unexpanded\expandafter{\ekv@ifempty{\#1}}%

```

(End definition for `\ekv@redirectunknownaux` and others. These functions are documented on page 4.)

The redirect code works by some simple loop over all the sets, which we already preprocessed in `\ekv@defredirectunknownaux`. For some optimisation we blow this up a bit code wise, essentially, all this does is `\ekv@ifdefined` or `\ekv@ifdefinedNoVal` in each set, if there is a match gobble the remainder of the specified sets and execute the key macro, else go on with the next set (to which the `<key>` and `<value>` are forwarded).

First we set up some code which is different depending on `\lastnamedcs` being available or not. All this is stored in a temporary macro to have pre-expanded `\ekv@name` constellations ready.

```

314     \unexpanded\expandafter{\ekv@name@key{##1}}%
315   }%
316   \unexpanded{\fi}%
317 }
318 \ekv@exparg{\protected\def\ekv@defsetmacro#1#2{\ekv@defsetmacro}}

```

(End definition for \ekv@defsetmacro.)

**\ekvifdefinedset**

```

319 \ekv@expargtwice{\def\ekvifdefinedset#1}%
320   {\expandafter\ekv@ifdefined\expandafter{\ekv@undefined@set{#1}}}

```

(End definition for `\ekvifdefinedset`. This function is documented on page 6.)

**\ekvset** Set up `\ekvset`, which should not be affected by active commas and equal signs. The equal signs are a bit harder to cope with and we'll do that later, but the active commas can be handled by just doing two comma-splitting loops one at actives one at others. That's why we define `\ekvset` here with a temporary meaning just to set up the things with two different category codes. #1 will be a `,13` and #2 will be a `=13`.

```

321 \begingroup
322 \def\ekvset#1#2{%
323 \endgroup
324 \ekv@exparg{\long\def\ekvset##1##2}{%
325   {%
326     \expandafter\expandafter\expandafter
327     \ekv@set\expandafter\csname\ekv@undefined@set{##1}\endcsname
328     \ekv@mark##2#1\ekv@stop#1{}}%
329 }

```

(End definition for `\ekvset`. This function is documented on page 4.)

**\ekv@set** `\ekv@set` will split the `\{key\}=\{value\}` list at active commas. Then it has to check whether there were unprotected other commas and resplit there.

```

330 \long\def\ekv@set##1##2#1{%
331   {%

```

Test whether we're at the end, if so invoke `\ekv@endset`,

```

332   \ekv@gobble@from@mark@to@stop##2\ekv@endset\ekv@stop

```

else go on with other commas.

```

333   \ekv@set@other##1##2,\ekv@stop,%
334 }

```

(End definition for `\ekv@set`.)

**\ekv@endset** `\ekv@endset` is a hungry little macro. It will eat everything that remains of `\ekv@set` and unbrace the sneaked stuff.

```

335 \long\def\ekv@endset
336   \ekv@stop\ekv@set@other##1\ekv@mark\ekv@stop,\ekv@stop,##2%
337   {##2}

```

(End definition for `\ekv@endset`.)

**\ekv@eq@other** **\ekv@eq@active** Splitting at equal signs will be done in a way that checks whether there is an equal sign and splits at the same time. This gets quite messy and the code might look complicated, but this is pretty fast (faster than first checking for an equal sign and splitting if one is found). The splitting code will be adapted for `\ekvset` and `\ekvpars` to get the most speed, but some of these macros don't require such adaptions. `\ekv@eq@other` and `\ekv@eq@active` will split the argument at the first equal sign and insert the macro which comes after the first following `\ekv@mark`. This allows for fast branching based on TeX's argument grabbing rules and we don't have to split after the branching if the equal sign was there.

```

338 \long\def\ekv@eq@other##1##2\ekv@mark##3##3##1\ekv@stop\ekv@mark##2}%
339 \long\def\ekv@eq@active##1##2\ekv@mark##3##3##1\ekv@stop\ekv@mark##2}

```

(End definition for \ekv@eq@other and \ekv@eq@active.)

\ekv@set@other The macro \ekv@set@other is guaranteed to get only single  $\langle key \rangle = \langle value \rangle$  pairs.  
340   \long\def\ekv@set@other##1##2,%  
341       {%

First we test whether we're done.

342       \ekv@gobble@from@mark@to@stop##2\ekv@endset@other\ekv@stop

If not we split at the equal sign of category other.

343       \ekv@eq@other##2\ekv@nil\ekv@mark\ekv@set@eq@other@a  
344           =\ekv@mark\ekv@set@eq@active

And insert the set name for the next recursion step of \ekv@set@other.

345       ##1%  
346       \ekv@mark  
347     }

(End definition for \ekv@set@other.)

\ekv@set@eq@other@a \ekv@set@eq@other@b The first of these two macros runs the split-test for equal signs of category active. It will only be inserted if the  $\langle key \rangle = \langle value \rangle$  pair contained at least one equal sign of category other and ##1 will contain everything up to that equal sign.

348   \long\def\ekv@set@eq@other@a##1\ekv@stop  
349       {%

350       \ekv@eq@active##1\ekv@nil\ekv@mark\ekv@set@eq@other@active  
351           #2\ekv@mark\ekv@set@eq@other@b  
352     }

The second macro will have been called by \ekv@eq@active if no active equal sign was found. All it does is remove the excess tokens of that test and forward the  $\langle key \rangle = \langle value \rangle$  pair to \ekv@set@pair. Normally we would have to also gobble an additional \ekv@mark after \ekv@stop, but this mark is needed to delimit \ekv@set@pair's argument anyway, so we just leave it there.

353   \ekv@exparg  
354       {%

355       \long\def\ekv@set@eq@other@b  
356           ##1\ekv@nil\ekv@mark\ekv@set@eq@other@active\ekv@stop\ekv@mark  
357           ##2\ekv@nil=\ekv@mark\ekv@set@eq@active  
358     }  
359   {\ekv@strip{##1}{\expandafter\ekv@set@pair\detokenize}\ekv@mark##2\ekv@nil}

(End definition for \ekv@set@eq@other@a and \ekv@set@eq@other@b.)

\ekv@set@eq@other@active \ekv@set@eq@other@active will be called if the  $\langle key \rangle = \langle value \rangle$  pair was wrongly split on an equal sign of category other but has an earlier equal sign of category active. ##1 will be the contents up to the active equal sign and ##2 everything that remains until the first found other equal sign. It has to reinsert the equal sign and forward things to \ekv@set@pair.

360   \ekv@exparg  
361       {%

362       \long\def\ekv@set@eq@other@active  
363           ##1\ekv@stop##2\ekv@nil#2\ekv@mark  
364           \ekv@set@eq@other@b\ekv@mark##3=\ekv@mark\ekv@set@eq@active  
365     }  
366   {\ekv@strip{##1}{\expandafter\ekv@set@pair\detokenize}\ekv@mark##2=##3}

(End definition for \ekv@set@eq@other@active.)

\ekv@set@eq@active \ekv@set@eq@active will be called when there was no equal sign of category other in the  $\langle key \rangle = \langle value \rangle$  pair. It removes the excess tokens of the prior test and split-checks for an active equal sign.

```
367 \long\def\ekv@set@eq@active
368     ##1\ekv@nil\ekv@mark\ekv@set@eq@other@a\ekv@stop\ekv@mark
369     {%
370         \ekv@eq@active##1\ekv@nil\ekv@mark\ekv@set@eq@active@
371         #2\ekv@mark\ekv@set@noeq
372     }
```

If an active equal sign was found in \ekv@set@eq@active we'll have to pass the now split  $\langle key \rangle = \langle value \rangle$  pair on to \ekv@set@pair.

```
373 \ekv@exparg
374     {\long\def\ekv@set@eq@active##1\ekv@stop##2\ekv@nil#2\ekv@mark\ekv@set@noeq}%
375     {\ekv@strip{##1}{\expandafter\ekv@set@pair\detokenize}\ekv@mark##2\ekv@nil}
```

(End definition for \ekv@set@eq@active and \ekv@set@eq@active@.)

\ekv@set@noeq If no active equal sign was found by \ekv@set@eq@active there is no equal sign contained in the parsed list entry. In that case we have to check whether the entry is blank in order to ignore it (in which case we'll have to gobble the set-name which was put after these tests by \ekv@set@other). Else this is a NoVal key and the entry is passed on to \ekv@set@key.

```
376 \edef\ekv@set@noeq
377     {%
378         \unexpanded
379         {%
380             \ekv@ifblank##1\ekv@nil\ekv@ifempty@B\ekv@set@was@blank
381             \ekv@ifempty@A\ekv@ifempty@B
382         }%
383         \unexpanded\expandafter
384         {\ekv@strip{##1}{\expandafter\ekv@set@key\detokenize}\ekv@mark}%
385     }
386 \ekv@exparg
387     {%
388         \long\def\ekv@set@noeq
389             ##1\ekv@nil\ekv@mark\ekv@set@eq@active@\ekv@stop\ekv@mark
390     }%
391     {\ekv@set@noeq}
392     \expandafter\def\expandafter\ekv@set@was@blank
393         \expandafter\ekv@ifempty@A\expandafter\ekv@ifempty@B
394         \ekv@strip{\ekv@mark##1}##2\ekv@mark
395     {\ekv@set@other}
```

(End definition for \ekv@set@noeq.)

\ekv@endset@other All that's left for \ekv@set@other is the macro which breaks the recursion loop at the end. This is done by gobbling all the remaining tokens.

```
396 \long\def\ekv@endset@other
397     \ekv@stop
398     \ekv@eq@other\ekv@mark\ekv@stop\ekv@nil\ekv@mark\ekv@set@eq@other@a
399     =\ekv@mark\ekv@set@eq@active
400     {\ekv@set}
```

(End definition for \ekv@endset@other.)

\ekvbrea<sup>k</sup> Provide macros that can completely stop the parsing of \ekvset, who knows what it'll be useful for.

\ekvbrea<sup>k</sup>PostSneak

```
401 \long\def\ekvbreak##1##2\ekv@stop##3{##1}
402 \long\def\ekvbreakPreSneak ##1##2\ekv@stop##3{##1##3}
403 \long\def\ekvbreakPostSneak##1##2\ekv@stop##3{##3##1}
```

(End definition for \ekvbrea<sup>k</sup>, \ekvbrea<sup>k</sup>PreSneak, and \ekvbrea<sup>k</sup>PostSneak. These functions are documented on page 6.)

\ekvsneak One last thing we want to do for \ekvset is to provide macros that just smuggle stuff after \ekvset's effects.

```
404 \long\def\ekvsneak##1##2\ekv@stop##3{##2\ekv@stop##1{##3##1}}
405 \long\def\ekvsneakPre##1##2\ekv@stop##3{##2\ekv@stop##1{##1##3}}
```

(End definition for \ekvsneak and \ekvsneakPre. These functions are documented on page 7.)

\ekvpars<sup>e</sup> Additionally to the \ekvset macro we also want to provide an \ekvpars<sup>e</sup> macro, that has the same scope as \keyval\_parse:NNn from expl3. This is pretty analogue to the \ekvset implementation, we just put an \unexpanded here and there instead of other macros to stop the \expanded on our output.

```
406 \long\def\ekvparse##1##2##3{\ekv@parse{##1}{##2}\ekv@mark##3#1\ekv@stop##1}
```

(End definition for \ekvpars<sup>e</sup>. This function is documented on page 5.)

(End definition for \ekv@parse@key.)

Finally really setting things up with \ekvset's temporary meaning:

```

487 }
488 \catcode`\,=13
489 \catcode`\-=13
490 \ekvset,=
```

**\ekvsetSneaked** This macro can be defined just by expanding \ekvsneak once after expanding \ekvset. To expand everything as much as possible early on we use a temporary definition.

```

491 \edef\ekvsetSneaked
492     {%
493         \unexpanded{\ekvsneak{#2}}%
494         \unexpanded\expandafter{\ekvset{#1}{#3}}%
495     }
496 \ekv@expargtwice{\long\def\ekvsetSneaked#1#2#3}{\ekvsetSneaked}
```

(End definition for \ekvsetSneaked. This function is documented on page 4.)

`\ekvchangeset` Provide a macro that is able to switch out the current `<set>` in `\ekvset`. This operation allows something similar to pgfkeys's `<key>/ .cd` mechanism. However this operation can be more expensive than `/ .cd` as we can't just redefine some token to reflect this, but have to switch out the set expandably, so this works similar to the `\ekvsneak` macros reading and reinserting things, but it only has to read and reinsert the remainder of the current key's replacement code.

```

497 \ekv@exparg{\def\ekvchangeset#1}%
498 {%
499     \expandafter\expandafter\expandafter
500     \ekv@changeset\expandafter\csname\ekv@undefined@set{#1}\endcsname\ekv@empty
501 }

```

(End definition for `\ekvchangeset`. This function is documented on page 7.)

`\ekv@changeset` This macro does the real change-out of `\ekvchangeset`. #2 will have a leading `\ekv@empty` so that braces aren't stripped accidentally, but that will not hurt and just expand to nothing in one step.

```
502 \long\def\ekv@changeset#1#2\ekv@set@other#3{#2\ekv@set@other#1}
```

(End definition for `\ekv@changeset`.)

`\ekv@set@pair` `\ekv@set@pair` gets invoked with the space and brace stripped and `\detokenized` key-name as its first, the value as the second, and the set name as the third argument. It provides tests for the key-macros and everything to be able to throw meaningful error messages if it isn't defined. We have two routes here, one if `\lastnamedcs` is defined and one if it isn't. The big difference is that if it is we can omit a `\csname` and instead just expand `\lastnamedcs` once to get the control sequence. If the macro is defined the value will be space and brace stripped and the key-macro called. Else branch into the error handling provided by `\ekv@set@pair`.

```

503 \ekv@if@lastnamedcs

```

(End definition for `\ekv@set@key` and others.)

**\ekvsetdef** Provide a macro to define a shorthand to use `\ekvset` on a specified `<set>`. To gain the maximum speed `\ekvset` is expanded twice by `\ekv@exparg` so that during runtime the macro storing the set name is already built and one `\expandafter` doesn't have to be used.

```

604 \ekv@expargtwice{\protected\def\ekvsetdef#1#2}%
605 {%
606     \romannumeral
607     \ekv@exparg{\ekv@zero\ekv@exparg{\long\def#1##1}%
608     {\ekvset{#2}{##1}}}%
609 }

```

(End definition for `\ekvsetdef`. This function is documented on page 5.)

**\ekvsetSneakeddef** And do the same for `\ekvsetSneaked` in the two possible ways, with a fixed sneaked argument and with a flexible one.

```

610 \ekv@expargtwice{\protected\def\ekvsetSneakeddef#1#2}%
611 {%
612     \romannumeral
613     \ekv@exparg{\ekv@zero\ekv@exparg{\long\def#1##1##2}%
614     {\ekvsetSneaked{#2}{##1}{##2}}}%
615 }
616 \ekv@expargtwice{\protected\def\ekvsetdefSneaked#1#2#3}%

```

```

617   {%
618     \romannumeral
619     \ekv@exparg{\ekv@zero\ekv@exparg{\long\def#1##1}}%
620     {\ekvsetSneaked{#2}{#3}{##1}}%
621   }

```

(End definition for `\ekvsetSneakeddef` and `\ekvsetdefSneaked`. These functions are documented on page 5.)

`\ekv@err` Since `\ekvset` is fully expandable as long as the code of the keys is (which is unlikely) we want to somehow throw expandable errors, in our case via undefined control sequences.

```

622 \def\ekv@err#1%
623 {%
624   \long\def\ekv@err##1{\expandafter\ekv@err@\@firstofone{#1##1.}\ekv@stop}%
625 }
626 \begingroup\expandafter\endgroup
627 \expandafter\ekv@err\csname ! expkv Error:\endcsname
628 \def\ekv@err@{\expandafter\ekv@gobbleto@stop}

```

(End definition for `\ekv@err` and `\ekv@err@`.)

`\ekv@err@common` Now we can use `\ekv@err` to set up some error messages so that we can later use those instead of the full strings.

```

629 \long\def\ekv@err@common #1#2{\expandafter\ekv@err@common@\string#2{#1}}
630 \ekv@exparg{\long\def\ekv@err@common@#1‘#2’ #3.#4#5}%
631   {\ekv@err{-#4 ('#5', set '#2')}%
632 \ekv@exparg{\long\def\ekv@err@unknown#1}{\ekv@err@common{unknown key}{#1}}%
633 \ekv@exparg{\long\def\ekv@err@noarg #1}{\ekv@err@common{value forbidden}{#1}}%
634 \ekv@exparg{\long\def\ekv@err@reqval #1}{\ekv@err@common{value required}{#1}}%
635 \ekv@exparg{\long\def\ekv@err@redirect@kv@notfound#1#2#3\ekv@stop}%
636   {\ekv@err{no key '#2' in sets #3}}%
637 \ekv@exparg{\def\ekv@err@redirect@k@notfound#1#2\ekv@stop}%
638   {\ekv@err{no NoVal key '#1' in sets #2}}%

```

(End definition for `\ekv@err@common` and others.)

Now everything that's left is to reset the category code of `@`.

```
639 \catcode`\@=\ekv@tmp
```
