

The `geometry` package

Hideo Umeki
`latexgeometry@gmail.com`

2010/02/12 v5.0

Abstract

This package provides a flexible and easy interface to page dimensions. You can change the page layout with intuitive parameters. For instance, if you want to set a margin to 2cm from each edge of the paper, you can go just `\usepackage[margin=2cm]{geometry}`. With `\newgeometry` command you can change the layout anywhere in the document.

1 Preface to version 5

- **Changing page layout mid-document.**

The new commands `\newgeometry{...}` and `\restoregeometry` allow users to change page dimensions in the middle of the document. `\newgeometry` is almost similar to `\geometry` except that `\newgeometry` disables all the options specified in the preamble and skips the papersize-related options: `landscape`, `portrait` and paper size options (such as `papersize`, `paper=a4paper` and so forth).

- **A new set of options to specify the layout area.**

The options specified for the area, in which the page dimensions are calculated, are added: `layout`, `layouts`, `layoutwidth`, `layoutheight` and so forth. These options would help to print the specified layout to a different sized paper. For example, with `a4paper` and `layout=a5paper`, the `geometry` package uses ‘A5’ layout to calculate margins with the paper size still ‘A4’.

- **A new driver option `xetex`.**

The new driver option `xetex` is added. The driver auto-detection routine has been revised so as to avoid an error with undefined control sequences. Note that ‘`geometry.cfg`’ in TeXLive, which disables the auto-detection routine and sets `pdftex`, is no longer necessary and has no problem even though it still exists. To set `xetex` is strongly recommended with XeLaTeX.

- **New paper size presets for JIS B-series.**

The `papersize` presets `b0j` to `b6j` for JIS (Japanese Industrial Standards) B-series are added.

- **Changing default for underspecified margin.**

In the previous version, if only one margin was specified, `bottom=1cm` for example, then `geometry` set the other margin with the margin ratio (1:1 by default for the vertical dimensions) and got `top=1cm` in this case. The version 5 sets the text-body size with the default `scale` (=0.7) and determine the unspecified margin. (See Section 6.5)

- **The option `showframe` works on every page.**

With `showframe` option, the page frames are shown on every page. In addition, the new option `showcrop` would print cropmarks showing the corners of the layout (the same as `paper` by default) on every page.

- **Loading `geometry.cfg` precedes processing class options.**

The previous version loaded `geometry.cfg` after processing the document class options. Now that the config file is loaded before processing the class options, you can change the behavior specified in `geometry.cfg` by adding options into `\documentclass` as well as `\usepackage` and `\geometry`.

- **Deleted options: `compat2` and `twosideshift`.** The version 5 has no longer compatibility with the previous ones. `compat2` and `twosideshift` are gone for simplicity.

2 Introduction

To set dimensions for page layout in L^AT_EX is not straightforward. You need to adjust several L^AT_EX native dimensions to place a text area where you want. If you want to center the text area in the paper you use, for example, you have to specify native dimensions as follows:

```
\usepackage{calc}
\setlength\textwidth{7in}
\setlength\textheight{10in}
\setlength\oddsidemargin{(\paperwidth-\textwidth)/2 - 1in}
\setlength\topmargin{(\paperheight-\textheight
                    -\headheight-\headsep-\footskip)/2 - 1in}.
```

Without package `calc`, the above example would need more tedious settings. Package `geometry` provides an easy way to set page layout parameters. In this case, what you have to do is just

```
\usepackage[text={7in,10in},centering]{geometry}.
```

Besides centering problem, setting margins from each edge of the paper is also troublesome. But `geometry` also make it easy. If you want to set each margin 1.5in, you can go

```
\usepackage[margin=1.5in]{geometry}
```

Thus, the `geometry` package has an auto-completion mechanism, in which unspecified dimensions are automatically determined. The `geometry` package will be also useful when you have to set page layout obeying the following strict instructions: for example,

The total allowable width of the text area is 6.5 inches wide by 8.75 inches high. The top margin on each page should be 1.2 inches from the top edge of the page. The left margin should be 0.9 inch from the left edge. The footer with page number should be at the bottom of the text area.

In this case, using `geometry` you can go

```
\usepackage[total={6.5in,8.75in},
            top=1.2in, left=0.9in, includefoot]{geometry}.
```

Setting a text area on the paper in document preparation system has some analogy to placing a window on the background in the window system. The name ‘`geometry`’ comes from the `-geometry` option used for specifying a size and location of a window in X Window System.

3 Page geometry

Figure 1 shows the page layout dimensions defined in the `geometry` package. The page layout contains a *total body* (printable area) and *margins*. The *total body* consists of a *body* (text area) with an optional *header*, *footer* and marginal notes (*marginpar*). There are four margins: *left*, *right*, *top* and *bottom*. For twosided documents, horizontal margins should be called *inner* and *outer*.

```
paper    : total body and margins
total body : body (text area) (optional head, foot and marginpar)
margins   : left(inner), right(outer), top and bottom
```

Each margin is measured from the corresponding edge of a paper. For example, left margin (inner margin) means a horizontal distance between the left (inner) edge of the paper and that of the total body. Therefore the left and top margins defined in `geometry` are different from the native dimensions `\leftmargin` and `\topmargin`. The size of a body (text area) can be modified by `\textwidth` and `\textheight`. The dimensions for paper, total body and margins have the following relations.

$$\text{paperwidth} = \text{left} + \text{width} + \text{right} \quad (1)$$

$$\text{paperheight} = \text{top} + \text{height} + \text{bottom} \quad (2)$$

The total body `width` and `height` would be defined:

$$\text{width} := \text{textwidth} (+\text{marginparsep} + \text{marginparwidth}) \quad (3)$$

$$\text{height} := \text{textheight} (+\text{headheight} + \text{headsep} + \text{footskip}) \quad (4)$$

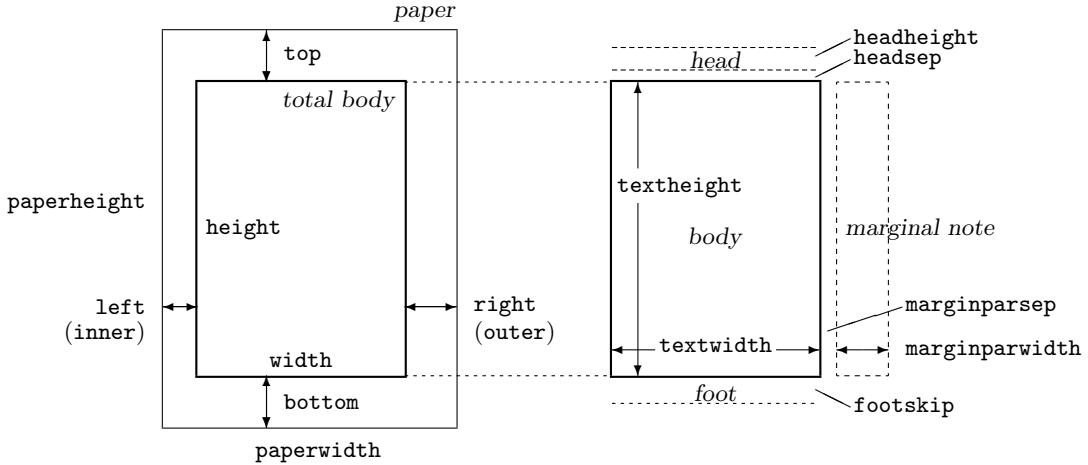

Figure 1: Dimension names used in the `geometry` package. `width`=`textwidth` and `height`=`textheight` by default. `left`, `right`, `top` and `bottom` are margins. If margins on verso pages are swapped by `twoside` option, margins specified by `left` and `right` options are used for the inside and outside margins respectively. `inner` and `outer` are aliases of `left` and `right` respectively.

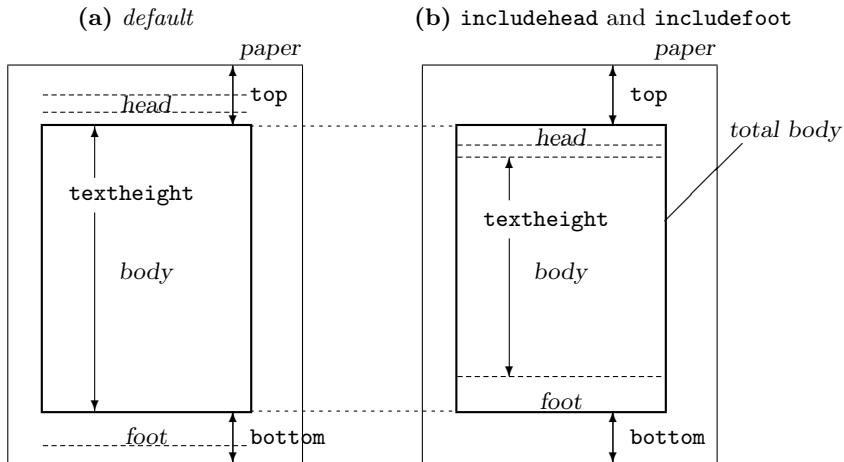

Figure 2: `includehead` and `includetfoot` include the head and foot respectively into *total body*.
(a) `height` = `textheight` (default). (b) `height` = `textheight` + `headheight` + `headsep` + `footskip` if `includehead` and `includetfoot`. If the top and bottom margins are specified, `includehead` and `includetfoot` result in shorter `textheight`.

In Equation (3) `width`=`textwidth` by default, while `marginparsep` and `marginparwidth` are included in `width` if `includemp` option is set `true`. In Equation (4), `height`=`textheight` by default. If `includehead` is set to `true`, `headheight` and `headsep` are considered as a part of `height`. In the same way, `includetfoot` takes `footskip` into `height`. Figure 2 shows how these options work in the vertical direction.

Thus, the page layout consists of three parts (lengths) in each direction: one body and two margins. If the two of them are explicitly specified, the other length is obvious and no need to be specified. Figure 3 shows a simple model of page dimensions. When a length L is given and is partitioned into the body b , the margins a and c , it's obvious that

$$L = a + b + c \quad (5)$$

The specification with two of the three (a, b and c) fixed explicitly is solvable. If two or more are left unspecified or ‘underspecified’, Equation (5) cannot be solved without any other relation between them. If all of them are specified, then it needs to check whether or not they satisfy Equation (5), that is too much specification or ‘overspecified’.

The `geometry` package has auto-completion mechanism that saves the trouble of specifying the page layout dimensions. For example, you can set

```
\usepackage[width=14cm, left=3cm]{geometry}
```

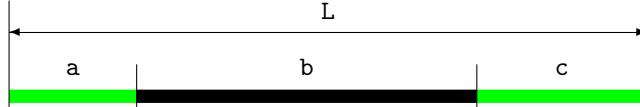

Figure 3: A simple model of page dimensions.

on A4 paper. In this case you don't have to set the right margin. The details of auto-completion will be described in Section 6.5.

4 User interface

4.1 Commands

The `geometry` package provides the following commands:

- `\geometry{<options>}`
- `\newgeometry{<options>}` and `\restoregeometry`
- `\savegeometry{<name>}` and `\loadgeometry{<name>}`

`\geometry{<options>}` changes the page layout according to the options specified in the argument. This command, if any, should be placed only in the preamble (before `\begin{document}`).

The `geometry` package may be used as part of a class or another package you use in your document. The command `\geometry` can overwrite some of the settings in the preamble. Multiple use of `\geometry` is allowed and then processed with the options concatenated. If `geometry` is not yet loaded, you can use only `\usepackage[<options>]{geometry}` instead of `\geometry`.

`\newgeometry{<options>}` changes the page layout mid-document. `\newgeometry` is almost similar to `\geometry` except that `\newgeometry` disables all the options specified by `\usepackage` and `\geometry` in the preamble and skips papersize-related options. `\restoregeometry` restores the page layout specified in the preamble. This command has no arguments. See Section 7 for details.

`\savegeometry{<name>}` saves the page dimensions as `<name>` where you put this command. `\loadgeometry{<name>}` loads the page dimensions saved as `<name>`. See Section 7 for details.

4.2 Optional argument

The `geometry` package adopts `keyval` interface '`<key>=<value>`' for the optional argument to `\usepackage`, `\geometry` and `\newgeometry`.

The argument includes a list of comma-separated `keyval` options and has basic rules as follows:

- Multiple lines are allowed, while blank lines are not.
- Any spaces between words are ignored.
- Options are basically order-independent. (There are some exceptions. See Section 6.2 for details.)

For example,

```
\usepackage[ a5paper , hmargin = { 3cm ,
                                .8in } , height
                                = 10in ]{geometry}
```

is equivalent to

```
\usepackage[height=10in,a5paper,hmargin={3cm,0.8in}]{geometry}
```

Some options are allowed to have sub-list, e.g. `{3cm,0.8in}`. Note that the order of values in the sub-list is significant. The above setting is also equivalent to the followings:

```
\usepackage{geometry}
\geometry{height=10in,a5paper,hmargin={3cm,0.8in}}
```

or

```
\usepackage[a5paper]{geometry}
\geometry{hmargin={3cm,0.8in},height=8in}
\geometry{height=10in}.
```

Thus, multiple use of `\geometry` just appends options.
`geometry` supports package `calc`¹. For example,

```
\usepackage{calc}
\usepackage[textheight=20\baselineskip+10pt]{geometry}
```

4.3 Option types

`geometry` options are categorized into four types:

1. Boolean type

takes a boolean value (`true` or `false`). If no value, `true` is set by default.

$\langle key \rangle = \text{true} \mid \text{false}$.
 $\langle key \rangle$ with no value is equivalent to $\langle key \rangle = \text{true}$.

Examples: `verbose=true`, `includehead`, `twoside=false`.

Paper name is the exception. The preferred paper name should be set with no values. Whatever value is given, it is ignored. For instance, `a4paper=XXX` is equivalent to `a4paper`.

2. Single-valued type

takes a mandatory value.

$\langle key \rangle = \langle value \rangle$.

Examples: `width=7in`, `left=1.25in`, `footskip=1cm`, `height=.86\paperheight`.

3. Double-valued type

takes a pair of comma-separated values in braces. The two values can be shortened to one value if they are identical.

$\langle key \rangle = \{\langle value1 \rangle, \langle value2 \rangle\}$.
 $\langle key \rangle = \langle value \rangle$ is equivalent to $\langle key \rangle = \{\langle value \rangle, \langle value \rangle\}$.

Examples: `hmargin={1.5in,1in}`, `scale=0.8`, `body={7in,10in}`.

4. Triple-valued type

takes three mandatory, comma-separated values in braces.

$\langle key \rangle = \{\langle value1 \rangle, \langle value2 \rangle, \langle value3 \rangle\}$

Each value must be a dimension or null. When you give an empty value or ‘*’, it means null and leaves the appropriate value to the auto-completion mechanism. You need to specify at least one dimension, typically two dimensions. You can set nulls for all the values, but it makes no sense.

Examples:

`hdivide={2cm,*,1cm}`, `vdivide={3cm,19cm, }`, `divide={1in,*,1in}`.

5 Option details

This section describes all the options available in `geometry`. Options with a dagger [†] are not available as a argument of `\newgeometry` (See Section 7).

¹CTAN: `macros/latex/required/tools`

5.1 Paper size

The options below set paper/media size and orientation.

\dagger `paper | papername`

specifies the paper size by name. `paper=<paper-name>`. For convenience, you can specify the paper name without `paper=`. For example, `a4paper` is equivalent to `paper=a4paper`.

\dagger `a0paper, a1paper, a2paper, a3paper, a4paper, a5paper, a6paper,`
`b0paper, b1paper, b2paper, b3paper, b4paper, b5paper, b6paper,`
`b0j, b1j, b2j, b3j, b4j, b5j, b6j,`
`ansiapaper, ansibpaper, ansicpaper, ansidpaper, ansiepaper,`
`letterpaper, executivepaper, legalpaper`

specifies paper name. The value part is ignored even if any. For example, the followings have the same effect: `a5paper`, `a5paper=true`, `a5paper=false` and so forth.

`a[0-6]paper` and `b[0-6]paper` are ISO A and B series of paper sizes. The JIS (Japanese Industrial Standards) A-series is identical to the ISO A-series, but the JIS B-series is different from the ISO B-series. `b[0-6]j` should be used for the JIS B-series.

\dagger `screen` a special paper size with $(W,H) = (225\text{mm}, 180\text{mm})$. For presentation with PC and video projector, “`screen,centering`” with ‘slide’ documentclass would be useful.

\dagger `paperwidth` width of the paper. `paperwidth=<length>`.

\dagger `paperheight` height of the paper. `paperheight=<length>`.

\dagger `papersize` width and height of the paper. `papersize={<width>,<height>}` or `papersize=<length>`.

\dagger `landscape` switches the paper orientation to landscape mode.

\dagger `portrait` switches the paper orientation to portrait mode. This is equivalent to `landscape=false`.

The options for paper names (e.g., `a4paper`) and orientation (`portrait` and `landscape`) can be set as document class options. For example, you can set `\documentclass[a4paper,landscape]{article}`, then `a4paper` and `landscape` are processed in `geometry` as well. This is also the case for `twoside` and `twocolumn` (see also Section 5.5).

5.2 Layout size

You can specify the layout area with options described in this section regardless of the paper size. The options would help to print the specified layout to a different sized paper. For example, with `a4paper` and `layout=a5paper`, the package uses ‘A5’ layout to calculate margins on ‘A4’ paper. The layout size defaults to the same as the paper. The options for the layout size are available in `\newgeometry`, so that you can change the layout size in the middle of the document. The paper size itself can’t be changed though. Figure 4 shows what the difference between `layout` and `paper` is.

`layout` specifies the layout size by paper name. `layout=<paper-name>`. All the paper names defined in `geometry` are available. See Section 5.1 for details.

`layoutwidth` width of the layout. `layoutwidth=<length>`.

`layoutheight` height of the layout. `layoutheight=<length>`.

`layoutsizer` width and height of the layout. `layoutsizer={<width>,<height>}` or `layoutsizer=<length>`.

`layouthoffset` specifies the horizontal offset from the left edge of the paper. `layouthoffset=<length>`.

`layoutvoffset` specifies the vertical offset from the top edge of the paper. `layoutvoffset=<length>`.

`layoutoffset` specifies both horizontal and vertical offsets. `layoutoffset={<hoffset>,<voftset>}` or `layoutsizer=<length>`.

5.3 Body size

The options specifying the size of *total body* are described in this section.

`hscale` ratio of width of *total body* to `\paperwidth`. `hscale=<h-scale>`, e.g., `hscale=0.8` is equivalent to `width=0.8\paperwidth`. (0.7 by default)

`vscale` ratio of height of *total body* to `\paperheight`, e.g., `vscale=<v-scale>`. (0.7 by default) `vscale=0.9` is equivalent to `height=0.9\paperheight`.

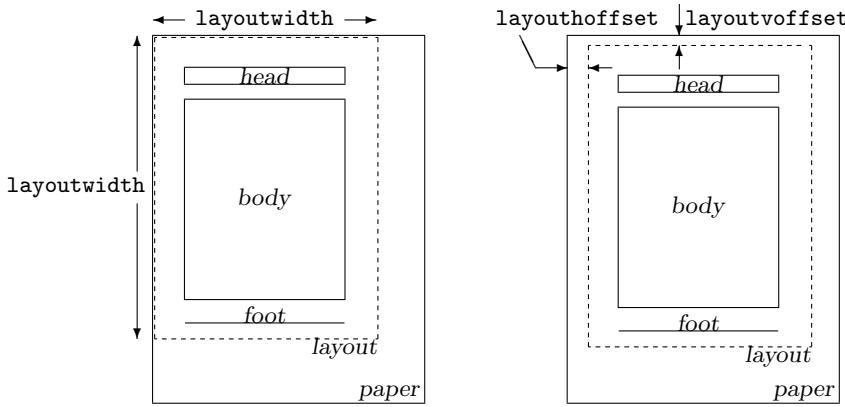

Figure 4: The dimensions related to the layout size. Note that the layout size defaults to the same size as the paper, so you don't have to specify layout-related options explicitly in most cases.

<code>scale</code>	ratio of <i>total body</i> to the paper. <code>scale={⟨h-scale⟩,⟨v-scale⟩}</code> or <code>scale=⟨scale⟩</code> . (0.7 by default)
<code>width totalwidth</code>	width of <i>total body</i> . <code>width=⟨length⟩</code> or <code>totalwidth=⟨length⟩</code> . This dimension defaults to <code>textwidth</code> , but if <code>includemp</code> is set to <code>true</code> , <code>width ≥ textwidth</code> because <code>width</code> includes the width of the marginal notes. If <code>textwidth</code> and <code>width</code> are specified at the same time, <code>textwidth</code> takes priority over <code>width</code> .
<code>height totalheight</code>	height of <i>total body</i> , excluding header and footer by default. If <code>includehead</code> or <code>includefoot</code> is set, <code>height</code> includes the head or foot of the page as well as <code>textheight</code> . <code>height=⟨length⟩</code> or <code>totalheight=⟨length⟩</code> . If both <code>textheight</code> and <code>height</code> are specified, <code>height</code> will be ignored.
<code>total</code>	width and height of <i>total body</i> . <code>total={⟨width⟩,⟨height⟩}</code> or <code>total=⟨length⟩</code> .
<code>textwidth</code>	specifies <code>\textwidth</code> , the width of <i>body</i> (the text area). <code>textwidth=⟨length⟩</code> .
<code>textheight</code>	specifies <code>\textheight</code> , the height of <i>body</i> (the text area). <code>textheight=⟨length⟩</code> .
<code>text body</code>	specifies both <code>\textwidth</code> and <code>\textheight</code> of the body of page. <code>body={⟨width⟩,⟨height⟩}</code> or <code>text=⟨length⟩</code> .
<code>lines</code>	enables users to specify <code>\textheight</code> by the number of lines. <code>lines=⟨integer⟩</code> .
<code>includehead</code>	includes the head of the page, <code>\headheight</code> and <code>\headsep</code> , into <i>total body</i> . It is set to <code>false</code> by default. It is opposite to <code>ignorehead</code> . See Figure 2 and Figure 5.
<code>includefoot</code>	includes the foot of the page, <code>\footskip</code> , into <i>total body</i> . It is opposite to <code>ignorefoot</code> . It is <code>false</code> by default. See Figure 2 and Figure 5.
<code>includeheadfoot</code>	sets both <code>includehead</code> and <code>includefoot</code> to <code>true</code> , which is opposite to <code>ignoreheadfoot</code> . See Figure 2 and Figure 5.
<code>includemp</code>	includes the margin notes, <code>\marginparwidth</code> and <code>\marginparsep</code> , into <i>body</i> when calculating horizontal calculation.
<code>includeall</code>	sets both <code>includeheadfoot</code> and <code>includemp</code> to <code>true</code> . See Figure 5.
<code>ignorehead</code>	disregards the head of the page, <code>headheight</code> and <code>headsep</code> , in determining vertical layout, but does not change those lengths. It is equivalent to <code>includehead=false</code> . It is set to <code>true</code> by default. See also <code>includehead</code> .
<code>ignorefoot</code>	disregards the foot of page, <code>footskip</code> , in determining vertical layout, but does not change that length. This option defaults to <code>true</code> . See also <code>includefoot</code> .
<code>ignoreheadfoot</code>	sets both <code>ignorehead</code> and <code>ignorefoot</code> to <code>true</code> . See also <code>includeheadfoot</code> .
<code>ignoreemp</code>	disregards the marginal notes in determining the horizontal margins (defaults to <code>true</code>). If marginal notes overrun the page, the warning message will be displayed when <code>verbose=true</code> . See also <code>includemp</code> and Figure 5.

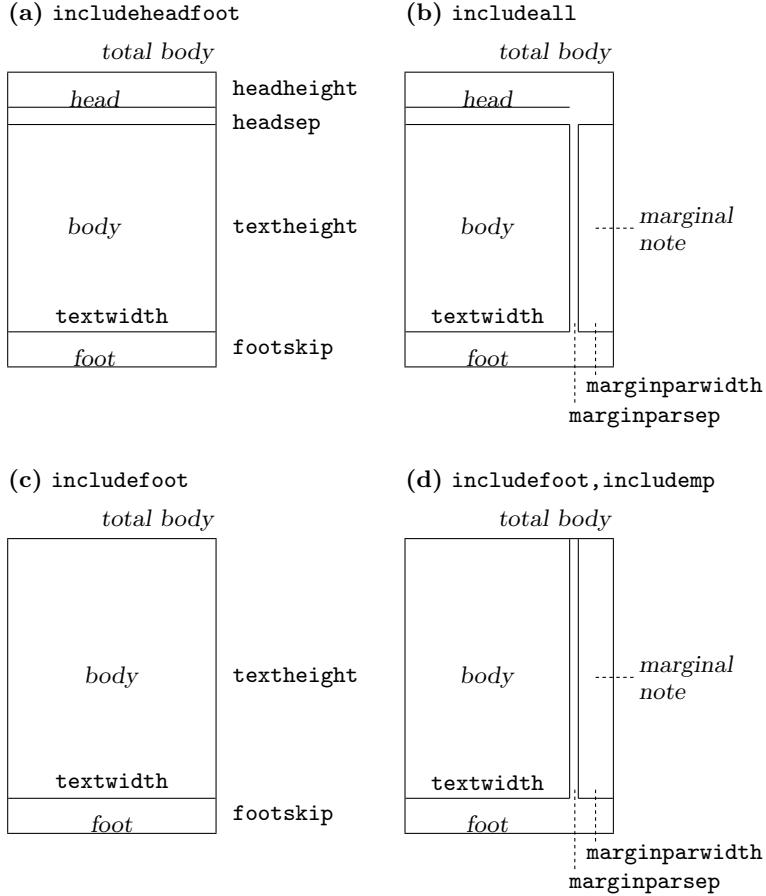

Figure 5: Sample layouts for *total body* with different switches. (a) `includeheadfoot`, (b) `includeall`, (c) `includefoot` and (d) `includefoot, includemp`. If `reversemp` is set to `true`, the location of the marginal notes are swapped on every page. Option `twoside` swaps both margins and marginal notes on verso pages. Note that the marginal note, if any, is printed despite `ignoremp` or `includemp=false` and overrun the page in some cases.

`ignoreall` sets both `ignoreheadfoot` and `ignoremp` to `true`. See also `includeall`.

`heightrounded`

This option rounds `\textheight` to n -times (n : an integer) of `\baselineskip` plus `\topskip` to avoid “underfull vbox” in some cases. For example, if `\textheight` is 486pt with `\baselineskip` 12pt and `\topskip` 10pt, then

$$(39 \times 12\text{pt} + 10\text{pt}) = 478\text{pt} < 486\text{pt} < 490\text{pt} (= 40 \times 12\text{pt} + 10\text{pt}),$$

as a result `\textheight` is rounded to 490pt. `heightrounded=false` by default.

Figure 5 illustrates various layouts with different layout modes. The dimensions for a header and a footer can be controlled by `nohead` or `nofoot` mode, which sets each length to 0pt directly. On the other hand, options with the prefix `ignore` do *not* change the corresponding native dimensions.

The following options can specify body and margins simultaneously with three comma-separated values in braces.

- `hdivide` horizontal partitions (left,width,right). `hdivide={⟨left margin⟩,⟨width⟩,⟨right margin⟩}`. Note that you should not specify all of the three parameters. The best way of using this option is to specify two of three and leave the rest with null(nothing) or ‘*’. For example, when you set `hdivide={2cm,15cm, }`, the margin from the right-side edge of page will be determined calculating `paperwidth-2cm-15cm`.
- `vdivide` vertical partitions (top,height,bottom). `vdivide={⟨top margin⟩,⟨height⟩,⟨bottom margin⟩}`.
- `divide` `divide={A,B,C}` is interpreted as `hdivide={A,B,C}` and `vdivide={A,B,C}`.

5.4 Margin size

The options specifying the size of the margins are listed below.

<code>left lmargin inner</code>	left margin (for oneside) or inner margin (for twoside) of <i>total body</i> . In other words, the distance between the left (inner) edge of the paper and that of <i>total body</i> . <code>left=<length>. inner</code> has no special meaning, just an alias of <code>left</code> and <code>lmargin</code> .
<code>right rmargin outer</code>	right or outer margin of <i>total body</i> . <code>right=<length></code> .
<code>top tmargin</code>	top margin of the page. <code>top=<length></code> . Note this option has nothing to do with the native dimension <code>\topmargin</code> .
<code>bottom bmargin</code>	bottom margin of the page. <code>bottom=<length></code> .
<code>hmargin</code>	left and right margin. <code>hmargin={<left margin>,<right margin>}</code> or <code>hmargin=<length></code> .
<code>vmargin</code>	top and bottom margin. <code>vmargin={<top margin>,<bottom margin>}</code> or <code>vmargin=<length></code> .
<code>margin</code>	<code>margin={A,B}</code> is equivalent to <code>hmargin={A,B}</code> and <code>vmargin={A,B}</code> . <code>margin=A</code> is automatically expanded to <code>hmargin=A</code> and <code>vmargin=A</code> .
<code>hmarginratio</code>	horizontal margin ratio of <code>left</code> (inner) to <code>right</code> (outer). The value of <code><ratio></code> should be specified with colon-separated two values. Each value should be a positive integer less than 100 to prevent arithmetic overflow, e.g., <code>2:3</code> instead of <code>1:1.5</code> . The default ratio is <code>1:1</code> for oneside, <code>2:3</code> for twoside.
<code>vmarginratio</code>	vertical margin ratio of <code>top</code> to <code>bottom</code> . The default ratio is <code>2:3</code> .
<code>marginratio ratio</code>	horizontal and vertical margin ratios. <code>marginratio={<horizontal ratio>,<vertical ratio>}</code> or <code>marginratio=<ratio></code> .
<code>hcentering</code>	sets auto-centering horizontally and is equivalent to <code>hmarginratio=1:1</code> . It is set to <code>true</code> by default for oneside. See also <code>hmarginratio</code> .
<code>vcentering</code>	sets auto-centering vertically and is equivalent to <code>vmarginratio=1:1</code> . The default is <code>false</code> . See also <code>vmarginratio</code> .
<code>centering</code>	sets auto-centering and is equivalent to <code>marginratio=1:1</code> . See also <code>marginratio</code> . The default is <code>false</code> . See also <code>marginratio</code> .
<code>twoside</code>	switches on twoside mode with left and right margins swapped on verso pages. The option sets <code>\@twoside</code> and <code>\@mparswitch</code> switches. See also <code>asymmetric</code> .
<code>asymmetric</code>	implements a twosided layout in which margins are not swapped on alternate pages (by setting <code>\oddsidemargin</code> to <code>\evensidemargin + bindingoffset</code>) and in which the marginal notes stay always on the same side. This option can be used as an alternative to the <code>twoside</code> option. See also <code>twoside</code> .
<code>bindingoffset</code>	removes a specified space from the lefthand-side of the page for oneside or the inner-side for twoside. <code>bindingoffset=<length></code> . This is useful if pages are bound by a press binding (glued, stitched, stapled ...). See Figure 6.
<code>hdivide</code>	See description in Section 5.3.
<code>vdivide</code>	See description in Section 5.3.
<code>divide</code>	See description in Section 5.3.

5.5 Native dimensions

The options below overwrite L^AT_EX native dimensions and switches for page layout (See the right-hand side in Figure 1).

<code>headheight head</code>	modifies <code>\headheight</code> , height of header. <code>headheight=<length></code> or <code>head=<length></code> .
<code>headsep</code>	modifies <code>\headsep</code> , separation between header and text (body). <code>headsep=<length></code> .
<code>footskip foot</code>	modifies <code>\footskip</code> , distance separation between baseline of last line of text and baseline of footer. <code>footskip=<length></code> or <code>foot=<length></code> .

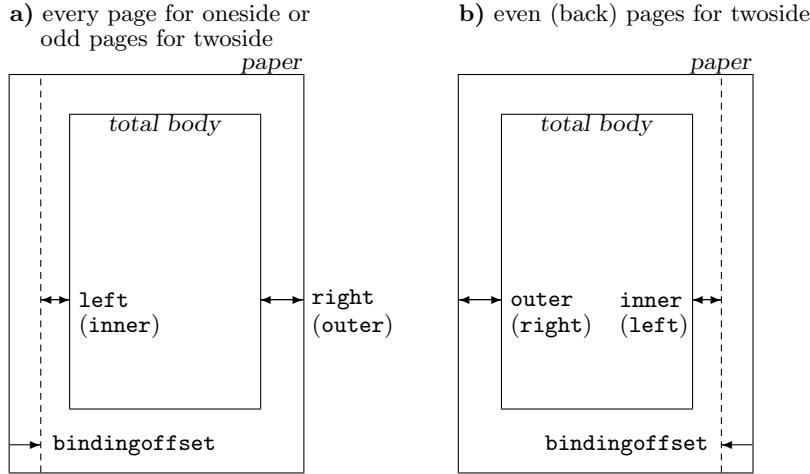

Figure 6: The option `bindingoffset` adds the specified length to the inner margin. Note that `twoside` option swaps the horizontal margins and the marginal notes together with `bindingoffset` on even pages (see b)), but `asymmetric` option suppresses the swap of the margins and marginal notes (but `bindingoffset` is still swapped).

<code>nohead</code>	eliminates spaces for the head of the page, which is equivalent to both <code>\headheight=0pt</code> and <code>\headsep=0pt</code> .
<code>nofoot</code>	eliminates spaces for the foot of the page, which is equivalent to <code>\footskip=0pt</code> .
<code>noheadfoot</code>	equivalent to <code>nohead</code> and <code>nofoot</code> , which means that <code>\headheight</code> , <code>\headsep</code> and <code>\footskip</code> are all set to 0pt.
<code>footnotesep</code>	changes the dimension <code>\skip\footins</code> , separation between the bottom of text body and the top of footnote text.
<code>marginparwidth marginpar</code>	modifies <code>\marginparwidth</code> , width of the marginal notes. <code>marginparwidth=<length></code> .
<code>marginparsep</code>	modifies <code>\marginparsep</code> , separation between body and marginal notes. <code>marginparsep=<length></code> .
<code>nomarginpar</code>	shrinks spaces for marginal notes to 0pt, which is equivalent to <code>\marginparwidth=0pt</code> and <code>\marginparsep=0pt</code> .
<code>columnsep</code>	modifies <code>\columnsep</code> , the separation between two columns in <code>twocolumn</code> mode.
<code>hoffset</code>	modifies <code>\hoffset</code> . <code>hoffset=<length></code> .
<code>voffset</code>	modifies <code>\voffset</code> . <code>voffset=<length></code> .
<code>offset</code>	horizontal and vertical offset. <code>offset=[<hoffset>,<voffset>]</code> or <code>offset=<length></code> .
<code>twocolumn</code>	sets <code>twocolumn</code> mode with <code>\@twocolumntrue</code> . <code>twocolumn=false</code> denotes <code>onecolumn</code> mode with <code>\@twocolumnfalse</code> .
<code>twoside</code>	sets both <code>\@twosidetrue</code> and <code>\@mparswitchtrue</code> . See Section 5.4.
<code>textwidth</code>	sets <code>\textwidth</code> directly. See Section 5.3.
<code>textheight</code>	sets <code>\textheight</code> directly. See Section 5.3.
<code>reversemp reversemarginpar</code>	makes the marginal notes appear in the left (inner) margin with <code>\@reversemargintrue</code> . The option doesn't change <code>includemp</code> mode. It's set <code>false</code> by default.

5.6 Drivers

The package supports drivers `dvips`, `dvipdfm`, `pdftex`, `xetex` and `vtx`. You can also set `dvipdfm` for `dvipdfmx` and `xdvipdfmx`. `pdftex` for `pdflatex`, and `vtx` for VTeX environment. The driver options are exclusive. The driver can be set by either `driver=<driver name>` or any of the drivers directly like `pdftex`. By default, `geometry` guesses the driver appropriate to the system in use. Therefore, you don't have to set a driver in most cases. However, if you want to use `dvipdfm`, you should specify it explicitly.

[†] `driver` specifies the driver with `driver=<driver name>`. `dvips`, `dvipdfm`, `pdftex`, `vtx`, `xetex`, `auto` and `none` are available as a driver name. The names except for `auto` and `none` can

be specified directly with the name without `driver=`. `driver=auto` makes the auto-detection work whatever the previous setting is. `driver=none` disables the auto-detection and sets no driver, which may be useful when you want to let other package work out the driver setting. For example, if you want to use `crop` package with `geometry`, you should call `\usepackage[driver=none]{geometry}` before the `crop` package.

[†] <code>dvips</code>	writes the paper size in dvi output with the <code>\special</code> macro. If you use <code>dvips</code> as a DVI-to-PS driver, for example, to print a document with <code>\geometry{a3paper,landscape}</code> on A3 paper in landscape orientation, you don't need options “ <code>-t a3 -t landscape</code> ” to <code>dvips</code> .
[†] <code>dvipdfm</code>	works like <code>dvips</code> except for landscape correction. You can set this option when using <code>dvipdfmx</code> and <code>xdvipdfmx</code> to process the dvi output.
[†] <code>pdftex</code>	sets <code>\pdfpagewidth</code> and <code>\pdfpageheight</code> internally.
[†] <code>xetex</code>	is the same as <code>pdftex</code> except for ignoring <code>\pdf{h,v}origin</code> undefined in XeLaTeX. This option is introduced in the version 5. Note that ‘ <code>geometry.cfg</code> ’ in TeXLive, which disables the auto-detection routine and sets <code>pdftex</code> , is no longer necessary, but has no problem even though it's left undeleted. Instead of <code>xetex</code> , you can specify <code>dvipdfm</code> with XeLaTeX if you want to use specials of <code>dvipdfm</code> XeTeX supports.
[†] <code>vtex</code>	sets dimensions <code>\mediawidth</code> and <code>\mediaheight</code> for VTeX. When this driver is selected (explicitly or automatically), <code>geometry</code> will auto-detect which output mode (DVI, PDF or PS) is selected in VTeX, and do proper settings for it.

If explicit driver setting is mismatched with the typesetting program in use, the default driver `dvips` would be selected.

5.7 Other options

The other useful options are described here.

[†] <code>verbose</code>	displays the parameter results on the terminal. <code>verbose=false</code> (default) still puts them into the log file.
[†] <code>reset</code>	sets back the layout dimensions and switches to the settings before <code>geometry</code> is loaded. Options given in <code>geometry.cfg</code> are also cleared. Note that this cannot reset <code>pass</code> and <code>mag</code> with <code>truedimen</code> . <code>reset=false</code> has no effect and cannot cancel the previous <code>reset=true</code> if any. For example, when you go
	<code>\documentclass[landscape]{article}</code> <code>\usepackage[twoside,reset,left=2cm]{geometry}</code>
	with <code>\ExecuteOptions{scale=0.9}</code> in <code>geometry.cfg</code> , then as a result, <code>landscape</code> and <code>left=2cm</code> remain effective, and <code>scale=0.9</code> and <code>twoside</code> are ineffective.
[†] <code>mag</code>	sets magnification value (<code>\mag</code>) and automatically modifies <code>\hoffset</code> and <code>\voffset</code> according to the magnification. <code>mag=<value></code> . Note that <code><value></code> should be an integer value with 1000 as a normal size. For example, <code>mag=1414</code> with <code>a4paper</code> provides an enlarged print fitting in <code>a3paper</code> , which is $1.414 (= \sqrt{2})$ times larger than <code>a4paper</code> . Font enlargement needs extra disk space. Note that setting <code>mag</code> should precede any other settings with ‘true’ dimensions, such as <code>1.5truein</code>, <code>2truecm</code> and so on. See also <code>truedimen</code> option.
[†] <code>truedimen</code>	changes all internal explicit dimension values into <i>true</i> dimensions, e.g., <code>1in</code> is changed to <code>1truein</code> . Typically this option will be used together with <code>mag</code> option. Note that this is ineffective against externally specified dimensions. For example, when you set “ <code>mag=1440, margin=10pt, truedimen</code> ”, margins are not ‘true’ but magnified. If you want to set exact margins, you should set like “ <code>mag=1440, margin=10truept, truedimen</code> ” instead.
[†] <code>pass</code>	disables all of the <code>geometry</code> options and calculations except <code>verbose</code> and <code>showframe</code> . It can be used for checking out the page layout of the <code>documentclass</code> , other packages and manual settings without <code>geometry</code> .
[†] <code>showframe</code>	shows visible frames for the text area and page, and the lines for the head and foot on the first page.

6 Processing options

6.1 Order of loading

If there's `geometry.cfg` somewhere TeX can find it, `geometry` loads it first. For example, in `geometry.cfg` you may write `\ExecuteOptions{a4paper}`, which specifies A4 paper as the default paper. Basically you can use all the options defined in `geometry` with `\ExecuteOptions{}`.

The order of loading in the preamble of your document is as follows:

1. `geometry.cfg` if it exists.
2. Options specified with `\documentclass[<options>]{...}`.
3. Options specified with `\usepackage[<options>]{geometry}`
4. Options specified with `\geometry{<options>}`, which can be called multiple times. (`reset` option will cancel the specified options ever given in `\usepackage{geometry}` or `\geometry`.)

6.2 Order of options

The specification of `geometry` options is order-independent, and overwrites the previous one for the same setting. For example,

`[left=2cm, right=3cm]` is equivalent to `[right=3cm, left=2cm]`.

The options called multiple times overwrite the previous settings. For example,

`[verbose=true, verbose=false]` results in `verbose=false`.

`[hmargin={3cm,2cm}, left=1cm]` is the same as `hmargin={1cm,2cm}`, where the left (or inner) margin is overwritten by `left=1cm`.

`reset` and `mag` are exceptions. The `reset` option removes all the `geometry` options (except `pass`) before it. If you set

```
\documentclass[landscape]{article}
\usepackage[margin=1cm,twoside]{geometry}
\geometry{a5paper, reset, left=2cm}
```

then `margin=1cm`, `twoside` and `a5paper` are removed, and is eventually equivalent to

```
\documentclass[landscape]{article}
\usepackage[left=2cm]{geometry}
```

The `mag` option should be set in advance of any other settings with ‘true’ length, such as `left=1.5truecm`, `width=5truein` and so on. The `\mag` primitive can be set before this package is called.

6.3 Priority

There are several ways to set dimensions of the *body*: `scale`, `total`, `text` and `lines`. The `geometry` package gives higher priority to the more concrete specification. Here is the priority rule for *body*.

$$\begin{array}{c} \text{priority:} \quad \text{low} \longrightarrow \text{high} \\ \left\{ \begin{array}{l} \text{hscale} \\ \text{vscale} \\ \text{scale} \end{array} \right\} < \left\{ \begin{array}{l} \text{width} \\ \text{height} \\ \text{total} \end{array} \right\} < \left\{ \begin{array}{l} \text{textwidth} \\ \text{textheight} \\ \text{text} \end{array} \right\} < \text{lines}. \end{array}$$

For example,

```
\usepackage[hscale=0.8, textwidth=7in, width=18cm]{geometry}
```

is the same as `\usepackage[textwidth=7in]{geometry}`. Another example:

```
\usepackage[lines=30, scale=0.8, text=7in]{geometry}
```

results in `[lines=30, textwidth=7in]`.

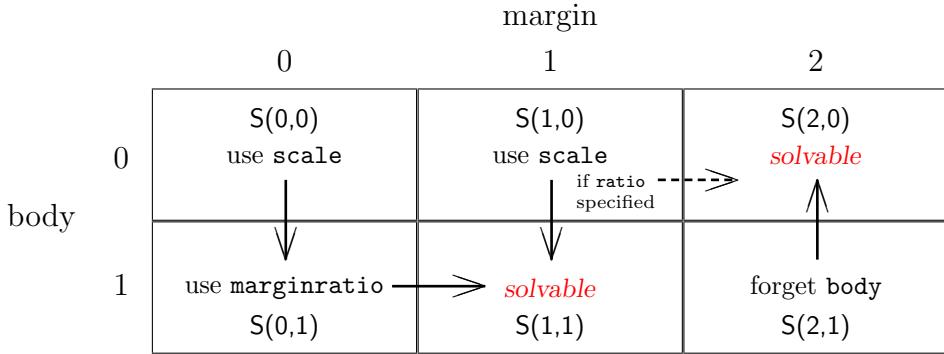

Figure 7: Specifications $S(0,0)$ to $S(2,1)$ and the completion rules (arrows). The horizontal and vertical denote the number of explicitly specified lengths for margin and body respectively. $S(m,b)$ denote a specification with a set of the numbers (margin,body)=(m,b).

6.4 Defaults

This section sums up the default settings for the auto-completion described later.

The default vertical margin ratio is 2/3, namely,

$$\text{top : bottom} = 2 : 3 \quad \text{default.} \quad (6)$$

As for the horizontal margin ratio, the default value depends on whether the document is onesided or twosided,

$$\text{left (inner) : right (outer)} = \begin{cases} 1 : 1 & \text{default for oneside,} \\ 2 : 3 & \text{default for twoside.} \end{cases} \quad (7)$$

Obviously the default horizontal margin ratio for oneside is ‘centering’.

The `geometry` package has the following default setting for *onesided* documents:

- `scale=0.7` (*body* is $0.7 \times \text{paper}$)
- `marginratio={1:1, 2:3}` (1:1 for horizontal and 2:3 for vertical margins)
- `ignoreall` (the header, footer, marginal notes are excluded when calculating the size of *body*.)

For *twosided* document with `twoside` option, the default setting is the same as *onesided* except that the horizontal margin ratio is set 2:3 as well.

Additional options overwrite the previous specified dimensions.

6.5 Auto-completion

Figure 7 shows schematically how many specification patterns exist and how to solve the ambiguity of the specifications. Each axis shows the numbers of lengths explicitly specified for body and margins. $S(m,b)$ presents the specification with a set of numbers (margin,body)=(m,b).

For example, the specification `width=14cm, left=3cm` is categorized into $S(1,1)$, which is an adequate specification. If you add `right=4cm`, it would be in $S(2,1)$ and overspecified. If only `width=14cm`, it’s in $S(0,1)$, underspecified.

The `geometry` package has the auto-completion mechanism, in which if the layout parameters are underspecified or overspecified, `geometry` works out the ambiguity using the defaults and other relations. Here are the specifications and the completion rules.

S(0,0) Nothing is specified. The `geometry` package sets *body* with the default `scale` (=0.7).

For example, `width` is set to be $0.7 \times \text{paperwidth}$. Thus $S(0,0)$ goes to $S(0,1)$. See $S(0,1)$.

S(0,1) Only *body* is specified, such as `width=7in, lines=20, body={20cm, 24cm}, scale=0.9` and so forth. Then `geometry` sets margins with the margin ratio. If the margin ratio is not specified, the default is used. The default vertical margin ratio is defined as

$$\text{top : bottom} = 2 : 3 \quad \text{default.} \quad (8)$$

As for the horizontal margin ratio, the default value depends on whether the document is onesided or twosided,

$$\text{left (inner)} : \text{right (outer)} = \begin{cases} 1 : 1 & \text{default for oneside,} \\ 2 : 3 & \text{default for twoside.} \end{cases} \quad (9)$$

For example, if `height=22cm` is specified on A4 paper, `geometry` calculates `top` margin as follows:

$$\begin{aligned} \text{top} &= (\text{paperheight} - \text{height}) \times 2/5 \\ &= (29.7 - 22) \times 2/5 = 3.08(\text{cm}) \end{aligned} \quad (10)$$

Thus `top` margin and body `height` have been determined, the specification for the vertical goes to $S(1,1)$ and all the parameters can be solved.

S(1,0) Only one margin is specified, such as `bottom=2cm`, `left=1in`, `top=3cm`, and so forth.

- If the margin ratio is *not* specified, `geometry` sets `body` with the default `scale` ($= 0.7$). For example, if `top=2.4cm` is specified, `geometry` sets

$$\text{height} = 0.7 \text{paperheight},$$

then $S(1,0)$ goes to $S(1,1)$, in which `bottom` is calculated with `paperheight - (height + top)` and results in 6.51cm on A4 paper.

- If the margin ratio is specified, such as `hmarginratio={1:2}`, `vratio={3:4}` and so forth, `geometry` sets the other margin with the specified margin ratio. For example, if a set of options “`top=2.4cm`, `vratio={3:4}`” is specified, `geometry` sets `bottom` to be 3.2cm calculating

$$\text{bottom} = \text{top}/3 \times 4 = 3.2\text{cm}$$

Thus $S(1,0)$ goes to $S(2,0)$.

Notes that the version 4 or earlier used to set the other margin with the margin ratio. In the version 5, therefore, with the same specification, the result will be different from the one in the version 4. For example, if only `top=2.4cm` is specified, you got `bottom=2.4cm` in the version 4 or earlier, but you will get `bottom=6.51cm` in the version 5.

S(2,1) The `body` and two `margins` are all specified, such as `vdivide={1in,8in,1.5in}`, “`left=3cm, width=13cm, right=4cm`” and so forth. Since `geometry` basically gives priority to `margins` if dimensions are overspecified, `geometry` forgets and resets `body`. For example, if you specify

```
\usepackage[a4paper, left=3cm, width=13cm, right=4cm]{geometry},
```

`width` is reset to be 14cm because the width of a A4 paper is 21cm long.

7 Changing layout mid-document

The version 5 provides the new commands `\newgeometry{...}` and `\restoregeometry`, which allow you to change page dimensions in the middle of the document. Unlike `\geometry` in the preamble, `\newgeometry` is available only after `\begin{document}`, resets all the options ever specified except for the `papersize`-related options: `landscape`, `portrait`, and paper size options (such as `papersize`, `paper=a4paper` and so forth), which can't be changed with `\newgeometry`.

The command `\restoregeometry` restores the page layout specified in the preamble (before `\begin{document}`) with the options to `\usepackage{geometry}` and `\geometry`.

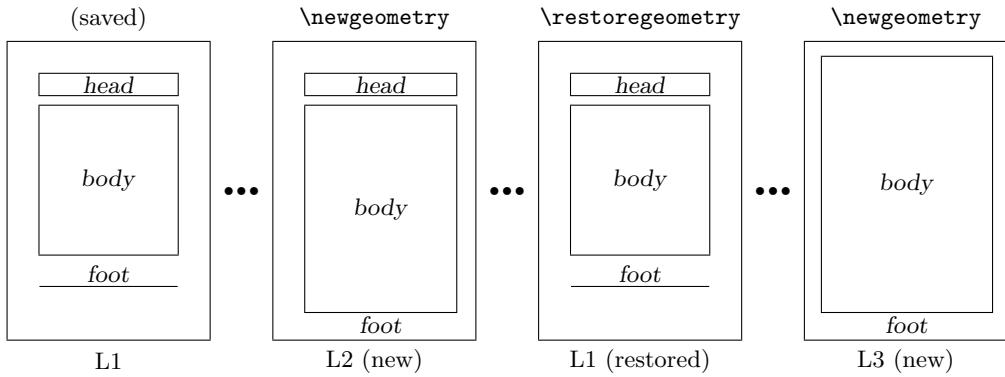

Note that both `\newgeometry` and `\restoregeometry` insert `\clearpage` where they are called.

Below is an example of changing layout mid-document. The layout L1 specified with `hmargin=3cm` (`left` and `right` margins are 3cm long) is changed to L2 with `left=3cm, right=1cm` and `bottom=0.1cm`. The layout L1 is restored with `\restoregeometry`.

```

\usepackage[hmargin=3cm]{geometry}
\begin{document}
    Layout L1
\newgeometry{left=3cm,right=1cm,bottom=0.1cm}
    Layout L2 (new)
\restoregeometry
    Layout L1 (restored)
\newgeometry{margin=1cm,includefoot}
    Layout L3 (new)
\end{document}

```

A set of commands `\savegeometry{<name>}` and `\loadgeometry{<name>}` is handy if you want to reuse more different layouts in your document. For example,

```

\usepackage[hmargin=3cm]{geometry}
\begin{document}
    L1
\newgeometry{left=3cm,right=1cm,bottom=0.1cm}
\savegeometry{L2}
    L2 (new, saved)
\restoregeometry
    L1 (restored)
\newgeometry{margin=1cm,includefoot}
    L3 (new)
\loadgeometry{L2}
    L2 (loaded)
\end{document}

```

8 Examples

- A onesided page layout with the text area centered in the paper. The examples below have the same result because the horizontal margin ratio is set 1:1 for oneside by default.
 - `centering`
 - `marginratio=1:1`
 - `vcentering`
- A twosided page layout with the inside offset for binding 1cm.
 - `twoside, bindingoffset=1cm`

In this case, `textwidth` is shorter than that of the default twosided document by $0.7 \times 1\text{cm} (=0.7\text{cm})$ because the default width of `body` is set with `scale=0.7` (which means `width = 0.7\paperwidth`).

- A layout with the left, right, and top margin 3cm, 2cm and 2.5in respectively, with `textheight` of 40 lines, and with the head and foot of the page included in *total body*. The two examples below have the same result.

– `left=3cm, right=2cm, lines=40, top=2.5in, includeheadfoot`
 – `hmargin={3cm,2cm}, tmargin=2.5in, lines=40, includeheadfoot`

- A layout with the height of *total body* 10in, the bottom margin 2cm, and the default width. The top margin will be calculated automatically. Each solution below results in the same page layout.

– `vdivide={*, 10in, 2cm}`
 – `bmargin=2cm, height=10in`
 – `bottom=2cm, textheight=10in`

Note that dimensions for *head* and *foot* are excluded from `height` of *total body*. An additional `includefoot` makes `\footskip` included in `totalheight`. Therefore, in the two cases below, `textheight` in the former layout is shorter than the latter (with 10in exactly) by `\footskip`. In other words, `height = textheight + footskip` when `includefoot=true` in this case.

– `bmargin=2cm, height=10in, includefoot`
 – `bottom=2cm, textheight=10in, includefoot`

- A layout with `textwidth` and `textheight` 90% of the paper and with *body* centered. Each solution below results in the same page layout.

– `scale=0.9, centering`
 – `text={.9\paperwidth,.9\paperheight}, ratio=1:1`
 – `width=.9\paperwidth, vmargin=.05\paperheight, marginratio=1:1`
 – `hdivide={*,0.9\paperwidth,*}, vdivide={*,0.9\paperheight,*}` (as for onesided documents)
 – `margin={0.05\paperwidth,0.05\paperheight}`

You can add `heightrounded` to avoid an “underfull vbox warning” like

```
Underfull \vbox (badness 10000) has occurred while \output is active.
```

See Section 5.3 for the detail description about `heightrounded`.

- A layout with the width of marginal notes 3cm and included in the width of *total body*. The following examples are the same.

– `marginparwidth=3cm, includemp`
 – `marginpar=3cm, ignoremp=false`

- A layout the full scale *body* of the paper with A5 paper in landscape. The following examples are the same.

– `a5paper, landscape, scale=1.0`
 – `landscape=TRUE, paper=a5paper, margin=0pt`

- A screen size layout appropriate to presentation with PC and video projector.

```
\documentclass{slide}
\usepackage[screen,margin=0.8in]{geometry}
...
\begin{slide}
...
\end{slide}
```

- A layout with fonts and spaces both enlarged from A4 to A3. In the case below, the resulted paper size is A3.

– `a4paper, mag=1414`.

If you want to have a layout with two times bigger fonts, but without changing paper size, you can go

– `letterpaper, mag=2000, truedimen.`

You can add `dvips` option, that is useful to preview it with proper paper size by `dviout` or `xdvi`.

- A complex page layout.

```
\usepackage[a5paper, landscape, twocolumn, twoside,
            left=2cm, hmarginratio=2:1, includemp, marginparwidth=43pt,
            bottom=1cm, foot=.7cm, includefoot, textheight=11cm, heightrounded,
            columnsep=1cm, dvips, verbose]{geometry}
```

Try typesetting it and checking out the result yourself. :-)

9 Known problems

- With `pdftex=true`, `mag ≠ 1000` and `truedimen`, `paperwidth` and `paperheight` shown in verbose mode are different from the real size of the resulted PDF. The PDF itself is correct anyway.
- With `pdftex=true`, `mag ≠ 1000`, *no* `truedimen`, and `hyperref`, `hyperref` should be loaded by `\usepackage` before `geometry`. Otherwise the resulted PDF size will become wrong.
- With `crop` package and `mag ≠ 1000`, `center` option of `crop` doesn't work well.
