2 l3draw-paths implementation

```

9 <*initex | package>
10 <@@=draw>

```

This sub-module covers more-or-less the same ideas as `pgfcorepathconstruct.code.tex`, though using the expandable FPU means that the implementation often varies. At present, equivalents of the following are currently absent:

- `\pgfpatharcto`, `\pgfpatharctoprecomputed`: These are extremely specialised and are very complex in implementation. If the functionality is required, it is likely that it will be set up from scratch here.
- `\pgfpathparabola`: Seems to be unused other than defining a *TikZ* interface, which itself is then not used further.
- `\pgfpathsine`, `\pgfpathcosine`: Need to see exactly how these need to work, in particular whether a wider input range is needed and what approximation to make.
- `\pgfpathcurvebetweentime`, `\pgfpathcurvebetweentimecontinue`: These don't seem to be used at all.

```

\l__draw_path_tmp_tl Scratch space.

(End definition for `\l__draw_path_tmp_tl`, `\l__draw_path_tmpa_fp`, and `\l__draw_path_tmpb_fp`.)

2.1 Tracking paths

`\g__draw_path_lastx_dim` The last point visited on a path.

`\g__draw_path_lasty_dim`
`14 \dim_new:N \g__draw_path_lastx_dim`
`15 \dim_new:N \g__draw_path_lasty_dim`

(End definition for `\g__draw_path_lastx_dim` and `\g__draw_path_lasty_dim`.)

`\g__draw_path_xmax_dim` The limiting size of a path.

`\g__draw_path_xmin_dim`
`16 \dim_new:N \g__draw_path_xmax_dim`
`\g__draw_path_ymax_dim`
`17 \dim_new:N \g__draw_path_xmin_dim`
`\g__draw_path_ymin_dim`
`18 \dim_new:N \g__draw_path_ymax_dim`
`19 \dim_new:N \g__draw_path_ymin_dim`

(End definition for `\g__draw_path_xmax_dim` and others.)

`__draw_path_update_limits:nn` Track the limits of a path and (perhaps) of the picture as a whole. (At present the latter is always true: that will change as more complex functionality is added.)

`__draw_path_reset_limits:`
`20 \cs_new_protected:Npn __draw_path_update_limits:nn #1#2`
`21 {`
`22 \dim_gset:Nn \g__draw_path_xmax_dim`

`28 \dim_gset:Nn \g__draw_path_ymin_dim`
`29 { \dim_min:nn \g__draw_path_ymin_dim {#2} }`
`30 \bool_if:NT \l_draw_bb_update_bool`
`31 {`
`32 \dim_gset:Nn \g__draw_xmax_dim`
`33 { \dim_max:nn \g__draw_xmax_dim {#1} }`
`34 \dim_gset:Nn \g__draw_xmin_dim`
`35 { \dim_min:nn \g__draw_xmin_dim {#1} }`
`36 \dim_gset:Nn \g__draw_ymax_dim`
`37 { \dim_max:nn \g__draw_ymax_dim {#2} }`
`38 \dim_gset:Nn \g__draw_ymin_dim`
`39 { \dim_min:nn \g__draw_ymin_dim {#2} }`
`40 }`
`41 }`
`42 \cs_new_protected:Npn __draw_path_reset_limits:`

`45 \dim_gset:Nn \g__draw_path_xmin_dim { \c_max_dim }`
`46 \dim_gset:Nn \g__draw_path_ymax_dim { -\c_max_dim }`
`47 \dim_gset:Nn \g__draw_path_ymin_dim { \c_max_dim }`
`48 }`

(End definition for `__draw_path_update_limits:nn` and `__draw_path_reset_limits:.`)

`__draw_path_update_last:nn` A simple auxiliary to avoid repetition.

`49 \cs_new_protected:Npn __draw_path_update_last:nn #1#2`
`50 {`
`51 \dim_gset:Nn \g__draw_path_lastx_dim {#1}`
`52 \dim_gset:Nn \g__draw_path_lasty_dim {#2}`

(End definition for _draw_path_update_last:nn.)

2.2 Corner arcs

At the level of path *construction*, rounded corners are handled by inserting a marker into the path: that is then picked up once the full path is constructed. Thus we need to set up the appropriate data structures here, such that this can be applied every time it is relevant.

\l__draw_corner_xarc_dim The two arcs in use.

```
\l__draw_corner_yarc_dim 54 \dim_new:N \l__draw_corner_xarc_dim
55 \dim_new:N \l__draw_corner_yarc_dim
```

(End definition for \l__draw_corner_xarc_dim and \l__draw_corner_yarc_dim.)

\l__draw_corner_arc_bool A flag to speed up the repeated checks.

```
56 \bool_new:N \l__draw_corner_arc_bool
```

(End definition for \l__draw_corner_arc_bool.)

\draw_path_corner_arc:nn Calculate the arcs, check they are non-zero.

```

65     { \bool_set_true:N \l__draw_corner_arc_bool }
66 }
```

(End definition for \draw_path_corner_arc:nn. This function is documented on page ??.)

__draw_path_mark_corner: Mark up corners for arc post-processing.

```
67 \cs_new_protected:Npn \__draw_path_mark_corner:
68 {
69   \bool_if:NT \l__draw_corner_arc_bool
70   {

(End definition for __draw_path_mark_corner:.)

2.5 Computed curves

More complex operations need some calculations. To assist with those, various constants are pre-defined.

`\draw_path_curveto:nn` A quadratic curve with one control point (x_c, y_c) . The two required control points are then

$$x_1 = \frac{1}{3}x_s + \frac{2}{3}x_c \quad y_1 = \frac{1}{3}y_s + \frac{2}{3}y_c$$

`\c__draw_path_curveto_a_fp`
`\c__draw_path_curveto_b_fp`

and

$$x_2 = \frac{1}{3}x_e + \frac{2}{3}x_c \quad x_2 = \frac{1}{3}y_e + \frac{2}{3}y_c$$

using the start (last) point (x_s, y_s) and the end point (x_e, y_e) .

The auxiliary is responsible for calculating the required points. The “magic” number required to determine the length of the control vectors is well-established for a right-angle: $\frac{4}{3}(\sqrt{2} - 1) = 0.552\,284\,75$. For other cases, we follow the calculation used by `pgf` but with the second common case of 60° pre-calculated for speed.

We can now calculate the required points. As everything here is non-expandable, that is best done by using x-type expansion to build up the tokens. The three points are calculated out-of-order, since finding the second control point needs the position of the end point. Once the points are found, fire-off the fundamental path operation and update the record of where we are up to. The final point has to be

\draw_path_ellipse:nnn Drawing an ellipse is an optimised version of drawing an arc, in particular reusing the same constant. We need to deal with the ellipse in four parts and also deal with moving to the right place, closing it and ending up back at the center. That is handled on a per-arc basis, each in a separate auxiliary for readability.

```

(End definition for \l__draw_path_use_clip_bool, \l__draw_path_use_fill_bool, and \l__draw_path_use_stroke_bool.)

Actions handled at the macro layer.

```

\l__draw_path_use_clear_bool
493 \bool_new:N \l__draw_path_use_bb_bool
494 \bool_new:N \l__draw_path_use_clear_bool

```

(End definition for \l__draw_path_use_bb_bool and \l__draw_path_use_clear_bool.)

There are a range of actions which can apply to a path: they are handled in a single function which can carry out several of them. The first step is to deal with the special case of clearing the path.

509     { \__draw_path_use:n { #1 , clear } }
510 }

```

Map over the actions and set up the data: mainly just booleans, but with the possibility to cover more complex cases. The business end of the function is a series of checks on the various flags, then taking the appropriate action(s).

This sub-module covers more-or-less the same ideas as `pgfcorepoints.code.tex`, though the approach taken to returning values is different: point expressions here are processed by expansion and return a co-ordinate pair in the form $\{\langle x \rangle\}\{\langle y \rangle\}$. Equivalents of following `pgf` functions are deliberately omitted:

- `\pgfpointorigin`: Can be given explicitly as `0pt,0pt`.
- `\pgfpoint`, `\pgfpointadd`, `\pgfpointdiff`, `\pgfpointscale`: Can be given explicitly.
- `\pgfextractx`, `\pgfextracty`: Available by applying `\use_i:nn/\use_ii:nn` or similar to the `x`-type expansion of a point expression.
- `\pgfgetlastxy`: Unused in the entire `pgf` core, may be emulated by `x`-type expansion of a point expression, then using the result.

In addition, equivalents of the following *may* be added in future but are currently absent:

- `\pgfpointcylindrical`, `\pgfpointsspherical`: The usefulness of these commands is not currently clear.

- `\pgfpointborderrectangle`, `\pgfpointborderellipse`: To be revisited once the semantics and use cases are clear.
- `\pgfqpoint`, `\pgfqpointscale`, `\pgfqpointpolar`, `\pgfqpointxy`, `\pgfqpointxyz`: The expandable approach taken in the code here, along with the absolute requirement for ε -TeX, means it is likely many use cases for these commands may be covered in other ways. This may be revisited as higher-level structures are constructed.

3.1 Support functions

Execute whatever code is passed to extract the x and y co-ordinates. The first argument here should itself absorb two arguments. There is also a version to deal with two co-ordinates: common enough to justify a separate function.

3.2 Polar co-ordinates

Polar co-ordinates may have either one or two lengths, so there is a need to do a simple split before the calculation. As the angle gets used twice, save on any expression evaluation there and force expansion.

```

3.3 Point expression arithmetic

These functions all take point expressions as arguments.

Only a single point expression so the expansion is done here. The outcome is the normalised vector from (0,0) in the direction of the point, *i.e.*

```

\draw_point_unit_vector:n
\__draw_point_unit_vector:nn

```

$$P_x = \frac{x}{\sqrt{x^2 + y^2}} \quad P_y = \frac{y}{\sqrt{x^2 + y^2}}$$

```

662 \cs_new:Npn \draw_point_unit_vector:n #1
663 { \__draw_point_process:nn { \__draw_point_unit_vector:nn } {#1} }
664 \cs_new:Npn \__draw_point_unit_vector:nn #1#2

666   \__draw_point_to_dim:n
667   { ( #1 , #2 ) / (sqrt(#1 * #1 + #2 * #2)) }
668 }

```

3.4 Intersection calculations

The intersection point P between a line joining points (x_1, y_1) and (x_2, y_2) with a second line joining points (x_3, y_3) and (x_4, y_4) can be calculated using the formulae

```

\draw_point_intersect_lines:nnnn
\__draw_point_intersect_lines:nnnnnnn
\__draw_point_intersect_lines:nnnnnnnn
\__draw_point_intersect_lines_aux:nnnnnnn
\__draw_point_intersect_lines_aux:fffff

```

$$P_x = \frac{(x_1 y_2 - y_1 x_2)(x_3 - x_4) - (x_3 y_4 - y_3 x_4)(x_1 - x_2)}{(x_1 - x_2)(y_3 - y_4) - (y_1 - y_2)(x_3 - x_4)}$$

and

$$P_y = \frac{(x_1 y_2 - y_1 x_2)(y_3 - y_4) - (x_3 y_4 - y_3 x_4)(y_1 - y_2)}{(x_1 - x_2)(y_3 - y_4) - (y_1 - y_2)(x_3 - x_4)}$$

The work therefore comes down to expanding the incoming data, then pre-calculating as many parts as possible before the final work to find the intersection. (Expansion and argument re-ordering is much less work than additional floating point calculations.)

```

669 \cs_new:Npn \draw_point_intersect_lines:nnnn #1#2#3#4

```
#1 x3
```

#2 y_3
 #3 x_4
 #4 y_4
 #5 x_1
 #6 y_1
 #7 x_2
 #8 y_2

so now just have to do all of the calculation.

Another long expansion chain to get the values in the right places. We have two circles, the first with center (a, b) and radius r , the second with center (c, d) and radius s . We use the intermediate values

$$\begin{aligned}
 e &= c - a \\
 f &= d - b \\
 p &= \sqrt{e^2 + f^2} \\
 k &= \frac{p^2 + r^2 - s^2}{2p}
 \end{aligned}$$

in either

$$\begin{aligned}
 P_x &= a + \frac{ek}{p} + \frac{f}{p}\sqrt{r^2 - k^2} \\
 P_y &= b + \frac{fk}{p} - \frac{e}{p}\sqrt{r^2 - k^2}
 \end{aligned}$$

or

$$P_x = a + \frac{ek}{p} - \frac{f}{p}\sqrt{r^2 - k^2}$$

$$P_y = b + \frac{fk}{p} + \frac{e}{p}\sqrt{r^2 - k^2}$$

depending on which solution is required. The rest of the work is simply forcing the appropriate expansion and shuffling arguments.

```

At this stage we have all of the information we need, fully expanded:

```

#1 r
#2 s
#3 a
#4 b
#5 c
#6 d
#7 n

```

Once we evaluate e and f , the co-ordinate (c, d) is no longer required: handy as we will need various intermediate values in the following.

```

708 \cs_new:Npn \__draw_point_intersect_circles_auxii:nnnnnnn #1#2#3#4#5#6#7

721 }
722 \cs_generate_variant:Nn \__draw_point_intersect_circles_auxiii:nnnnnnn { ff }

```

We now have p : we pre-calculate $1/p$ as it is needed a few times and is relatively expensive. We also need r^2 twice so deal with that here too.

We now have all of the intermediate values we require, with one division carried out up-front to avoid doing this expensive step twice:

#1 k
#2 $1/p$
#3 r^2
#4 e
#5 f
#6 a
#7 b
#8 n

There are some final pre-calculations, k/p , $\frac{\sqrt{r^2-k^2}}{p}$ and the usage of n , then we can yield a result.

y'_1 &= (1-p)y_1 + py_2 \\
x'_2 &= (1-p)x_2 + px_3 \\
y'_2 &= (1-p)y_2 + py_3 \\
x'_3 &= (1-p)x_3 + px_4 \\
y'_3 &= (1-p)y_3 + py_4
\end{aligned}$$

In the second stage, we can drop the final point

$$\begin{aligned}
x''_1 &= (1-p)x'_1 + px'_2 \\
y''_1 &= (1-p)y'_1 + py'_2 \\
x''_2 &= (1-p)x'_2 + px'_3 \\
y''_2 &= (1-p)y'_2 + py'_3
\end{aligned}$$

and for the final stage only need one set of calculations

$$\begin{aligned}
P_x &= (1-p)x''_1 + px''_2 \\
P_y &= (1-p)y''_1 + py''_2
\end{aligned}$$

Of course, this does mean a lot of calculations and expansion!

5.1 Managing soft paths

There are two linked aims in the code here. The most significant is to provide a way to modify paths, for example to shorten the ends or round the corners. This means that the path cannot be written piecemeal as specials, but rather needs to be held in macros. The second aspect that follows from this is performance: simply adding to a single macro a piece at a time will have poor performance as the list gets long so we use \tl_build... functions.

Each marker (operation) token takes two arguments, which makes processing more straight-forward. As such, some operations have dummy arguments, whilst others have to be split over several tokens. As the code here is at a low level, all dimension arguments are assumed to be explicit and fully-expanded.

\g__draw_softpath_main_tl The soft path itself.

The loop can take advantage of the fact that all soft path operations are made up of a token followed by two arguments. At this stage, there is a simple split: have we round a round point. If so, is there any actual rounding to be done: if the arcs have come through zero, just ignore it. In cases where we are not at a corner, we simply move along the path, allowing for any new part starting due to a moveto.

We now have all of the data needed to construct a rounded corner: all that is left to do is to work out the detail! At this stage, we have details of where the corner itself is (#4, #5), and where the next point is (#1, #2). There are two types of calculations to do. First, we need to interpolate from those two points in the direction of the corner, in order to work out where the curve we are adding will start and end. From those, plus the points we already have, we work out where the control points will lie. All of this is done in an expansion to avoid multiple calls to `\tl_put_right:Nx`. The end point of the line is worked out up-front and saved: we need that if dealing with a close-path operation.

To deal with a close-path operation, we need to do some manipulation. It needs to be treated as a line operation for rounding, and then have the close path operation re-added at the point where the curve ends. That means saving the end point in the calculation step (see earlier), and shuffling a lot.
