# The `l3str-format` package: formatting strings of characters\*

The L<sup>A</sup>T<sub>E</sub>X3 Project<sup>†</sup>

Released 2012/07/09

## 1 Format specifications

In this module, we introduce the notion of a string  $\langle format \rangle$ . The syntax follows that of Python's `format` built-in function. A  $\langle format specification \rangle$  is a string of the form

$$\langle format specification \rangle = [[\langle fill \rangle]\langle alignment \rangle][\langle sign \rangle][\langle width \rangle][.\langle precision \rangle][\langle style \rangle]$$

where each [...] denotes an independent optional part.

- $\langle fill \rangle$  can be any character: it is assumed to be present whenever the second character of the  $\langle format specification \rangle$  is a valid  $\langle alignment \rangle$  character.
- $\langle alignment \rangle$  can be `<` (left alignment), `>` (right alignment), `^` (centering), or `=` (for numeric types only).
- $\langle sign \rangle$  is allowed for numeric types; it can be `+` (show a sign for positive and negative numbers), `-` (only put a sign for negative numbers), or a space (show a space or a `-`).
- $\langle width \rangle$  is the minimum number of characters of the result: if the result is naturally shorter than this  $\langle width \rangle$ , then it is padded with copies of the character  $\langle fill \rangle$ , with a position depending on the choice of  $\langle alignment \rangle$ . If the result is naturally longer, it is not truncated.
- $\langle precision \rangle$ , whose presence is indicated by a period, can have different meanings depending on the type.
- $\langle style \rangle$  is one character, which controls how the given data should be formatted. The list of allowed  $\langle styles \rangle$  depends on the type.

The choice of  $\langle alignment \rangle =$  is not implemented yet.

---

## 2 Formatting various data-types

---

<code>\tl_format:Nn</code> *	<code>\tl_format:nn {&lt;token list&gt;} {&lt;format specification&gt;}</code>
<code>\tl_format:(cn nn)</code> *	Converts the <i>&lt;token list&gt;</i> to a string according to the <i>&lt;format specification&gt;</i> . The <i>&lt;style&gt;</i> , if present, must be <b>s</b> . If <i>&lt;precision&gt;</i> is given, all characters of the string representation of the <i>&lt;token list&gt;</i> beyond the first <i>&lt;precision&gt;</i> characters are discarded.
<hr/>	
<code>\seq_format:Nn</code> *	<code>\seq_format:Nn {&lt;sequence&gt;} {&lt;format specification&gt;}</code>
<code>\seq_format:cn</code> *	Converts each item in the <i>&lt;sequence&gt;</i> to a string according to the <i>&lt;format specification&gt;</i> , and concatenates the results.
<hr/>	
<code>\int_format:nn</code> *	<code>\int_format:nn {&lt;intexpr&gt;} {&lt;format specification&gt;}</code>
	Evaluates the <i>&lt;integer expression&gt;</i> and converts the result to a string according to the <i>&lt;format specification&gt;</i> . The <i>&lt;precision&gt;</i> argument is not allowed. The <i>&lt;style&gt;</i> can be <b>b</b> for binary output, <b>d</b> for decimal output (this is the default), <b>o</b> for octal output, <b>X</b> for hexadecimal output (using capital letters).
<hr/>	
<code>\fp_format:nn</code> *	<code>\fp_format:nn {&lt;fpexpr&gt;} {&lt;format specification&gt;}</code>
	Evaluates the <i>&lt;floating point expression&gt;</i> and converts the result to a string according to the <i>&lt;format specification&gt;</i> . The <i>&lt;precision&gt;</i> defaults to 6. The <i>&lt;style&gt;</i> can be
	<ul style="list-style-type: none"><li>• <b>e</b> for scientific notation, with one digit before and <i>&lt;precision&gt;</i> digits after the decimal separator, and an integer exponent, following <b>e</b>;</li><li>• <b>f</b> for a fixed point notation, with <i>&lt;precision&gt;</i> digits after the decimal separator and no exponent;</li><li>• <b>g</b> for a general format, which uses style <b>f</b> for numbers in the range <math>[10^{-4}, 10^{&lt;precision&gt;})</math> and style <b>e</b> otherwise.</li></ul>

## 3 Possibilities, and things to do

- Provide a token list formatting *<style>* which keeps the last *<precision>* characters rather than the first *<precision>*.

## 4 l3str-format implementation

```
1 <*initex | package>
2 <@@=str>
3 <*package>
4 \ProvidesExplPackage
5   {<ExplFileName>}{<ExplFileDate>}{<ExplFileVersion>}{<ExplFileDescription>
```

```

6 \RequirePackage{l3str}
7 \end{package}

```

## 4.1 Helpers

```

\use:nf A simple variant.
\use:fnf
8 \cs_generate_variant:Nn \use:nn { nf }
9 \cs_generate_variant:Nn \use:nnn { fnf }
(End definition for \use:nf and \use:fnf)

```

```

\tl_to_str:f A simple variant.
10 \cs_generate_variant:Nn \tl_to_str:n { f }
(End definition for \tl_to_str:f)

```

```

\__str_format_if_digit:NTF Here we expect #1 to be a character with category other, or \s__stop.
11 \prg_new_conditional:Npnn \__str_format_if_digit:N #1 { TF }
12 {
13   \if_int_compare:w \c_nine < 1 #1 \exp_stop_f:
14   \prg_return_true: \else: \prg_return_false: \fi:
15 }
(End definition for \__str_format_if_digit:NTF)

```

```

\__str_format_put:nw Put #1 after an \s__stop delimiter.
\__str_format_put:ow
\__str_format_put:fw
16 \cs_new:Npn \__str_format_put:nw #1 #2 \s__stop { #2 \s__stop #1 }
17 \cs_generate_variant:Nn \__str_format_put:nw { o , f }
(End definition for \__str_format_put:nw, \__str_format_put:ow, and \__str_format_put:fw)

```

## 4.2 Parsing a format specification

```

\__str_format_parse:n The goal is to parse
\__str_format_parse_i:NN
\__str_format_parse_ii:nN
\__str_format_parse_iii:nN
\__str_format_parse_iv:nwN
\__str_format_parse_v:nN
\__str_format_parse_vi:nwN
\__str_format_parse_vii:nN
\__str_format_parse_end:nwn
18 \cs_new:Npn \__str_format_parse:n #1
19 {
20   \exp_last_unbraced:Nf \__str_format_parse_i:NN
21   \__str_to_other:n {#1} \s__stop \s__stop {#1}
22 }
23 \cs_new:Npx \__str_format_parse_i:NN #1#2

69 }
70 \cs_new:Npn \_str_format_parse_end:nwn #1 #2 \s__stop \s__stop #3
71 {
72   \tl_if_empty:nF {#2}
73   { \_msg_kernel_expandable_error:nmn { str } { invalid-format } {#3} }
74   #1
75 }

```

(End definition for `\_str_format_parse:n` This function is documented on page ??.)

### 4.3 Alignment

The 4 functions in this section receive an  $\langle body \rangle$ , a  $\langle sign \rangle$ , a  $\langle width \rangle$  and a  $\langle fill \rangle$  character (exactly one character). For non-numeric types, the  $\langle sign \rangle$  is empty and the  $\langle body \rangle$  is the (other) string we want to format. For numeric types, we wish to format  $\langle sign \rangle \langle body \rangle$

(both are other strings). The alignment types <, > and ^ keep *<sign>* and *<body>* together. The = alignment type, however, inserts the padding between the *<sign>* and the *<body>*, hence the need to keep those separate.

`\_str_format_align_<:nnnN`      `\_str_format_align_<:nnnN {<body>} {<sign>} {<width>} <fill>`  
 Aligning “*<sign>* *<body>*” to the left entails appending #4 the correct number of times. Then convert the result to a string.

```

76 \cs_new:cpn { \_str_format_align_<:nnnN } #1#2#3#4
77   {
78     \use:nf { #2 #1 }
79     {
80       \prg_replicate:nn
81         { \int_max:nn { #3 - \_str_count_unsafe:n { #2 #1 } } { 0 } }
82         {#4}
83     }
84   }

```

(End definition for `\_str_format_align_<:nnnN`)

`\_str_format_align_>:nnnN`      `\_str_format_align_>:nnnN {<body>} {<sign>} {<width>} <fill>`  
 Aligning “*<sign>* *<body>*” to the right entails prepending #4 the correct number of times. Then convert the result to a string.

```

85 \cs_new:cpn { \_str_format_align_>:nnnN } #1#2#3#4
86   {
87     \prg_replicate:nn
88       { \int_max:nn { #3 - \_str_count_unsafe:n { #2 #1 } } { 0 } }
89       {#4}
90     #2 #1
91   }

```

(End definition for `\_str_format_align_>:nnnN`)

`\_str_format_align_^:nnnN`      `\_str_format_align_^:nnnN {<body>} {<sign>} {<width>} <fill>`  
 Centering “*<sign>* *<body>*” entails prepending and appending #4 the correct number of times. If the number of #4 to be added is odd, we add one more after than before.

```

92 \cs_new:cpn { \_str_format_align_^:nnnN } #1#2#3#4
93   {
94     \use:fnf
95     {
96       \prg_replicate:nn
97         {
98           \int_max:nn \c_zero
99             { #3 - \_str_count_unsafe:n { #2 #1 } - \c_one }
100           / \c_two
101         }
102         {#4}
103     }
104     { #2 #1 }
105     {
106       \prg_replicate:nn

```

```

107     {
108         \int_max:nn \c_zero
109         { #3 - \_str_count_unsafe:n { #2 #1 } }
110         / \c_two
111     }
112     {#4}
113 }
114 }

```

```

\_str_format_align=:nnnN \_str_format_align=:nnnN {<body>} {<sign>} {<width>} {<fill>}

```

The special numeric alignment = means that we insert the appropriate number of copies of #4 between the *<sign>* and the *<body>*. Then convert the result to a string.

```

115 \cs_new:cpn { \_str_format_align=:nnnN } #1#2#3#4
116 {
117     \use:nf {#2}
118     {
119         \prg_replicate:nn
120         { \int_max:nn { #3 - \_str_count_unsafe:n { #2 #1 } } { 0 } }
121         {#4}
122     }
123     #1
124 }

```

(End definition for \\_str\_format\_align=:nnnN)

## 4.4 Formatting token lists

**\tl\_format:Nn** Call \\_str\_format\_tl:NNNnnNn to read the parsed *<format specification>*. Then convert the result to a string.

```

\tl_format:cn \tl_format:cn the result to a string.
\tl_format:nn
125 \cs_new_nopar:Npn \tl_format:Nn { \exp_args:No \tl_format:nn }
126 \cs_generate_variant:Nn \tl_format:Nn { c }
127 \cs_new:Npn \tl_format:nn #1#2
128 {
129     \tl_to_str:f
130     {
131         \exp_last_unbraced:Nf \_str_format_tl:NNNnnNn
132         { \_str_format_parse:n {#2} }
133         {#1}
134     }
135 }

```

(End definition for \tl\_format:Nn, \tl\_format:cn, and \tl\_format:nn These functions are documented on page ??.)

```

\_str_format_tl:NNNnnNn \_str_format_tl:NNNnnNn {<fill>} {<alignment>} {<sign>} {<width>} {<precision>}
{<style>} {<token list>}

```

First check that the *<alignment>* is not =, and set the default alignment ? to <. Place the modified information after a trailing \s\_\_stop for later retrieval. Then check that there was no *<sign>*. The width will be useful later, store it after \s\_\_stop. Afterwards, check the *<precision>*: if it is empty, we will eventually use the whole string, otherwise we

will only use a substring, starting at the index 1, and ending at #5. There is a need to use the “unsafe” function, as otherwise leading spaces would get stripped by f-expansion. Finally, check that the *style* is ? or s.

```

136 \cs_new:Npn \__str_format_tl:NNNnnNn #1#2#3#4#5#6
137 {
138   \token_if_eq_charcode:NNTF #2 =
139   {
140     \__msg_kernel_expandable_error:nnnn
141     { str } { invalid-align-format } {#2} {t1}
142     \__str_format_put:nw { #1 < }
143   }
144   {
145     \token_if_eq_charcode:NNTF #2 ?
146     { \__str_format_put:nw { #1 < } }
147     { \__str_format_put:nw { #1 #2 } }
148   }
149   \token_if_eq_charcode:NNF #3 ?
150   {
151     \__msg_kernel_expandable_error:nnnn
152     { str } { invalid-sign-format } {#3} {t1}
153   }
154   \__str_format_put:nw { {#4} }
155   \tl_if_empty:nTF {#5}
156   { \__str_format_put:nw { \use:n { } } }
157   { \__str_format_put:nw { \__str_substr_unsafe:nnn { {1} {#5} } } }
158   \token_if_eq_charcode:NNF #6 s
159   {
160     \token_if_eq_charcode:NNF #6 ?
161     {
162       \__msg_kernel_expandable_error:nnnn
163       { str } { invalid-style-format } {#6} {t1}
164     }
165   }
166   \__str_format_tl_s:NNnnNNn
167   \s__stop
168 }

```

(End definition for \\_\_str\_format\_tl:NNNnnNn)

```

\__str_format_tl_s:NNnnNNn \__str_format_tl_s:NNnnNNn \s__stop <function> {<arguments>} {<width>}
<fill> <alignment> {<token list>}

```

The *function* and *arguments* are built in such a way that f-expanding *function* {*other string*} *arguments* yields the piece of the *other string* that we want to output. The *other string* is built from the *token list* by f-expanding \\_\_str\_to\_other:n.

```

169 \cs_new:Npn \__str_format_tl_s:NNnnNNn #1#2#3#4#5#6#7
170 {
171   \exp_args:Nc \exp_args:Nf
172   { \__str_format_align_#6:nnnN }
173   { \exp_args:Nf #2 { \__str_to_other:n {#7} } #3 }
174   { }

```

```

175     {#4} #5
176   }
(End definition for \_str_format_tl_s:NNnnNNn)

```

## 4.5 Formatting sequences

`\seq_format:Nn` Each item is formatted as a token list according to the specification. First parse the format and expand the sequence, then loop through the items. Eventually, convert to a string.

```

177 \cs_new:Npn \seq_format:Nn #1#2
178   {
179     \tl_to_str:f
180     { \_str_format_seq:of {#1} { \_str_format_parse:n {#2} } }
181   }
182 \cs_generate_variant:Nn \seq_format:Nn { c }
(End definition for \seq_format:Nn and \seq_format:cn These functions are documented on page ??.)

```

`\_str_format_seq:nn` The first argument is the contents of a seq variable. The second is a parsed *(format specification)*. Set up the loop.

`\_str_format_seq:of`

```

183 \cs_new:Npn \_str_format_seq:nn #1#2
184   {
185     \_str_format_seq_loop:nnNn { } {#2}
186     #1
187     { ? \_str_format_seq_end:w } { }
188   }
189 \cs_generate_variant:Nn \_str_format_seq:nn { of }
(End definition for \_str_format_seq:nn and \_str_format_seq:of)

```

`\_str_format_seq_loop:nnNn`

```

\_str_format_seq_loop:nnNn {<done>} {<parsed format>} \_seq_item:n
{<item>}

```

The first argument is the result of formatting the items read so far. The third argument is a single token (`\_seq_item:n`), until we reach the end of the sequence, where `\use_none:n #3` ends the loop.

```

190 \cs_new:Npn \_str_format_seq_loop:nnNn #1#2#3#4
191   {
192     \use_none:n #3
193     \exp_args:Nf \_str_format_seq_loop:nnNn
194     { \use:nf {#1} { \_str_format_tl:NNnnNn #2 {#4} } }
195     {#2}
196   }
(End definition for \_str_format_seq_loop:nnNn)

```

`\_str_format_seq_end:w`

Pick the right piece in the loop above.

```

197 \cs_new:Npn \_str_format_seq_end:w #1#2#3#4 { \use_ii:nnn #3 }
(End definition for \_str_format_seq_end:w)

```

## 4.6 Formatting integers

`\int_format:nn` Evaluate the first argument and feed it to `\__str_format_int:nn`.

```
198 \cs_new:Npn \int_format:nn #1
199   { \exp_args:Nf \__str_format_int:nn { \int_eval:n {#1} } }
(End definition for \int_format:nn This function is documented on page 3.)
```

`\__str_format_int:nn` Parse the *format specification* and feed it to `\__str_format_int:NNNnnNn`. Then convert the result to a string

```
200 \cs_new:Npn \__str_format_int:nn #1#2
201   {
202     \tl_to_str:f
203     {
204       \exp_last_unbraced:Nf \__str_format_int:NNNnnNn
205       { \__str_format_parse:n {#2} }
206       {#1}
207     }
208   }
```

(End definition for `\__str_format_int:nn`)

`\__str_format_int:NNNnnNn` `\__str_format_int:NNNnnNn` *fill* *alignment* *sign* *{width}* *{precision}* *{style}* *{integer}*

First set the default alignment ? to >. Place the modified information after a trailing `\s__stop` for later retrieval. Then check the *sign*: if the integer is negative, always put -. Otherwise, if the format's *sign* is ~, put a space (with category "other"); if it is + put +; if it is - (default), put nothing, represented as a brace group. The width #4 will be useful later, store it after `\s__stop`. Afterwards, check that the *precision* was absent. Finally, dispatch depending on the *style*.

```
209 \cs_new:Npn \__str_format_int:NNNnnNn #1#2#3#4#5#6#7
210   {
211     \token_if_eq_charcode:NNTF #2 ?
212     { \__str_format_put:nw { #1 > } }
213     { \__str_format_put:nw { #1 #2 } }
214     \int_compare:nNnTF {#7} < \c_zero
215     { \__str_format_put:nw { - } }
216     {
217       \str_case:nnn {#3}
218       {
219         { ~ } { \__str_format_put:ow { \c_catcode_other_space_tl } }
220         { + } { \__str_format_put:nw { + } }
221       }
222       { \__str_format_put:nw { { } } }
223     }
224     \__str_format_put:nw { {#4} }
225     \tl_if_empty:nF {#5}
226     {
227       \__msg_kernel_expandable_error:nnnn
228       { str } { invalid-precision-format } {#5} {int}
229     }
```

```

230 \str_case:nnn {#6}
231 {
232   { ? } { \__str_format_int:NwnnNNn \use:n }
233   { d } { \__str_format_int:NwnnNNn \use:n }

237 }
238 {
239   \__msg_kernel_expandable_error:nnnn
240   { str } { invalid-style-format } {#6} { int }
241   \__str_format_int:NwnnNNn \use:n
242 }
243 \s__stop {#7}
244 }

```

(End definition for `\__str_format_int:NwnnNNn`)

```

\__str_format_int:NwnnNNn \__str_format_int:NwnnNNn <function> \s__stop {<width>} {<sign>} <fill>
<alignment> {<integer>}

```

Use the `format_align` function corresponding to the `<alignment>`, with the following arguments:

- the string formed by combining the sign `#4` with the result of converting the absolute value of the `<integer>` `#7` according to the conversion function `#1`;
- the `<width>`;
- the `<fill>` character.

```

245 \cs_new:Npn \__str_format_int:NwnnNNn #1#2 \s__stop #3#4#5#6#7
246 {
247   \exp_args:Nc \exp_args:Nf
248   { \__str_format_align_#6:nnnN }
249   { #1 { \int_abs:n {#7} } }
250   {#4}
251   {#3} #5
252 }

```

(End definition for `\__str_format_int:NwnnNNn`)

## 4.7 Formatting floating points

`\fp_format:nn` Evaluate the first argument to an internal floating point number, and feed it to `\__str_format_fp:nn`.

```

253 \cs_new:Npn \fp_format:nn #1
254 { \exp_args:Nf \__str_format_fp:nn { \__fp_parse:n {#1} } }

```

(End definition for `\fp_format:nn` This function is documented on page 3.)

`\__str_format_fp:nn` Parse the *format specification* and feed it to `\__str_format_fp:NNNnnNn`. Then convert the result to a string

```

255 \cs_new:Npn \__str_format_fp:nn #1#2
256   {
257     \tl_to_str:f
258     {
259       \exp_last_unbraced:Nf \__str_format_fp:NNNnnNw
260       { \__str_format_parse:n {#2} }
261       #1
262     }
263   }

```

(End definition for `\__str_format_fp:nn`)

`\__str_format_fp:NNNnnNw` `\__str_format_fp:NNNnnNw <fill> <alignment> <format sign> {<width>} {<precision>} <style> \s_fp \__fp_chk:w <fp type> <fp sign> <fp body> ;`

First set the default alignment ? to >. Place the modified information after a trailing `\s__stop` for later retrieval. Then check the *format sign* and the *fp sign*: if the floating point is negative, always put -. Otherwise (including nan), if the format's *sign* is ~, put a space (with category "other"); if it is + put +; if it is - (default), put nothing, represented as a brace group. The width #4 will be useful later, store it after `\s__stop`. Afterwards, check the *precision*: if it was not given, replace it by 6 (default precision). Finally, dispatch depending on the *style*.

```

264 \cs_new:Npn \__str_format_fp:NNNnnNw
265   #1#2#3#4#5#6 \s__fp \__fp_chk:w #7 #8

359       . . ;
360       {#4}
361     }
362   }
363 \cs_new:Npn \_str_format_fp_f_ii:wwwn #1 . #2 . #3 ; #4
364   {
365     \use:nf
366     { #1 . #2 }
367     { \prg_replicate:nn { #4 - \_str_count_unsafe:n {#2} } {0} }
368   }

```

(End definition for `\_str_format_fp_f:wn` This function is documented on page 3.)

`\__str_format_fp_g:wn`  
`\__str_format_fp_g_ii:wn`

With the `g` type, first filter out special cases. In the normal case, round to `#4` significant figures, then test the exponent: if  $-4 \leq \langle exponent \rangle < \langle precision \rangle$ , use the presentation type `f`, otherwise use the presentation type `e`. Also, a `<precision>` of 0 is treated like a precision of 1. Actually, we don't reuse the `e` and `f` auxiliaries, because we want to trim trailing zeros. Thankfully, this is done by `\fp_to_decimal:n` and `\fp_to_scientific:n`, acting on the (absolute value of the) rounded value.

```

369 \cs_new:Npn \__str_format_fp_g:wn \s__fp \__fp_chk:w #1#2 ; #3
370   {
371     \int_case:nnn {#1}

403 \__msg_kernel_new:nnn { str } { invalid-style-format }
404   { Invalid-style~'#1'~for~type~'#2'. }

```

## 4.9 Todos

- Check what happens during floating point formatting when a number is rounded to 0 or  $\infty$ . I think the `e` and `f` types break horribly.
