## 1 Introduction

THE `LTXKEYS` PACKAGE provides facilities for creating and managing keys in the manner of the `keyval` and `xkeyval` packages, but it is intended to be more robust and faster than these earlier packages. Its robustness emanates from, inter alia, its ability to preserve braces in key values throughout parsing. The need to preserve braces in key values without expecting the user to double braces emerges often in parsing keys. This is the case in, e.g., the `xwatermark` package, but consider also the possibility of passing all the following options to a package at once, where ‘`layout`’ is a package or class option or key<sup>★1</sup>:

```

1 \pkgoptions{%
2   opt1=val1,opt2=val2,
3   layout={left=3cm,right=3cm,top=2.5cm,bottom=2.5cm,include=true}
4 }
```

As a practical example, the `amtools` package has the command `\amloadmodules` with the syntax

<sup>★1</sup> It should be noted that if a value of the demonstrative option `layout` is expandable, then the option can’t be passed by `\documentclass` without preloading a robust options parser like `kvoptions-patch`, `xkvltxp`, `catoptions`, or `ltxkeys` package. In fact, L<sup>A</sup>T<sub>E</sub>X’s native options processor can’t handle options with values. The `ltxkeys` package, unlike the `xkeyval` package, can be loaded before `\documentclass`.

<sup>5</sup> `\amloadmodules{\<base>}{\<modules>}`

Braced key values

where `<modules>` is a comma-separated `<key>=<value>` list. Like the above ‘layout’ option, each key of `\amloadmodules` may have a value (representing module options) that is itself a comma-separated `<key>=<value>` list.

Well, the type of robustness described here isn’t actually difficult to implement within the `xkeyval` package. This is indeed what the `keyreader` package does: it patches some commands of the `xkeyval` package to achieve this robustness. That said, we have to indicate that the `ltxkeys` package implements this robustness intrinsically and it has many more features than the `xkeyval` and `keyreader` packages.

The `ltxkeys` package is faster<sup>\*2</sup> than the `xkeyval` package mainly because it avoids character-wise parsing of key values (which is called ‘selective sanitization’ by the `xkeyval` package). Moreover, it is faster to normalize a comma-separated or `<key>=<value>` list than trim leading and trailing spaces of each element of the list (as the `xkeyval` package does), since not all the elements of the list will normally have leading and trailing spaces. In fact, the chances are that only less than 50 percent of the elements of the list will have such spaces. As another example of optimization, anyone familiar with the implementation of the `xkeyval` package would have noticed that the macro `\XKV@srsstate`, which (in order to allow `\setkeys` to be re-entrant) pushes and pops the states of some important functions in the package, loops over all the functions both when pushing and popping. In the `ltxkeys` package, pushing and popping functions together involve looping over the functions only once. And, unlike in the `xkeyval` package, higher order functions are undefined as soon as they are no longer needed, to avoid clogging up the stack. No additional looping is required for this.

In setting keys, the `ltxkeys` package loops over not only families, as in the `xkeyval` package, but also over key prefixes. The same strategy applies when the `ltxkeys` package tries to establish if a key is defined or not.

While some user interfaces of the `ltxkeys` package are similar to those of the `xkeyval` package, there are important differences in several areas of syntax, semantics, and internal implementation. The `ltxkeys` package also provides additional facilities (beyond the `xkeyval` package) for defining and managing keys. Several types of keys (including ordinary keys, command keys, style keys, choice keys, boolean and biboolean keys) can be efficiently created and managed. In the `ltxkeys` package, the notions of ‘pre-setting’ and ‘post-setting’ keys are similar to those of the `xkeyval` package. But the `ltxkeys` package introduces additional concepts in this respect: ‘initialized’ and ‘launched’ keys. The latter are special preset keys. The pointer system of the `xkeyval` package, which was available only at key-setting time, is now available also at key definition time. One more type of pointer (`\needvalue`) has been introduced to require users of ‘need-value keys’ to supply values for those keys.

Rather than simply issue an error for undefined keys when setting keys, the `ltxkeys` package provides the ‘undefined keys’ and ‘undefined options’ handlers, which are user-customizable. Other new concepts include ‘definable keys’, ‘cross-family keys’, ‘option keys’, ‘non-option keys’, ‘handled keys’, ‘pathkeys’, ‘key commands’, ‘key environments’, accessing the saved value of a key outside

---

<sup>\*2</sup> Because of the multitude of functions provided by the `ltxkeys` package, it may actually slow down when executing some tasks, depending on the task at hand. The package option `tracingkeys`, for example, does slow down processing. And automatically initiating keys after definition, as done by the commands `\ltxkeys@definekeys` and `\ltxkeys@declarekeys`, also affects processing speed; so does ‘launching keys,’ which first presets absent keys with their default values before setting the current keys (i.e., keys whose values are provided by the user at the moment of setting keys that belong to a family). Then, as in the `xkeyval` package, there are the commands for presetting and post-setting keys.

`\setkeys` or similar commands, and declaring multiple keys and options (of all genre) using only one command.

**Note 1.1** It is not advisable to alias the commands of the `xkeyval` package to the commands of the `ltxkeys` package. There are many existing packages that rely on the `xkeyval` package and aliasing commands that are used by other packages can cause confusion<sup>★3</sup>.

### 1.1 Motivation

What are the *raison d'être* and origins of the `ltxkeys` package? Well, I decided to write this package as I grappled with some practical problems of key parsing while developing version 1.5.0 of the `xwatermark` package. The tasks proved more challenging than I had initially thought and, despite its commendable and widely deployed features, I found the `xkeyval` package inadequate in some respects. As mentioned earlier, all the functions of the `ltxkeys` package can be employed for general key management in L<sup>A</sup>T<sub>E</sub>X beyond the `xwatermark` package. Indeed the `ltxkeys` package can be used as a more robust replacement for the `xkeyval` package, of course with modifications of names and some syntaxes. The `xkeyval` package has been frozen since August 2008.

## 2 Package options

The package options are listed in Table 1. The package options can be passed via `\documentclass`<sup>★4</sup>, `\RequirePackage` or `\usepackage` as follows:

6	<code>\documentclass[tracingkeys,keyparser={}]{}</code>
7	or
8	<code>\usepackage[tracingkeys,keyparser={}]{ltxkeys}</code>

Example: Package options

They can also be passed via the command `\ltxkeys@options`:

9	New macro: <code>\ltxkeys@options</code>
	<code>\ltxkeys@options{tracingkeys=false,keyparser={;}}</code>

Table 1: Package options

Option	Default	Meaning
<code>tracingkeys</code>	<code>false</code>	The global boolean switch that determines if information should be logged in the transcript file for some tasks in the package. See note 1.1
<code>keyparser</code>	<code>;</code>	The list parser used by some internal loops in defining keys. 1.2
<code>keydepthlimit</code>	<code>4</code>	This is used to guard against erroneous infinite re-entrance of the package's key-setting commands. The default value of 4 means that neither of these commands can ordinarily be nested beyond level 4. 1.3

*Continued on next page*

<sup>★3</sup> A user of version 0.0.1 of the `ltxkeys` package had sought to do this.

<sup>★4</sup> Passing `ltxkeys` package options via `\documentclass` implies that the package is loaded after `\documentclass`. As mentioned elsewhere, the `ltxkeys` package can be loaded before or after `\documentclass`.

<i>Continued from last page</i>		
Option	Default	Meaning
<code>reservenopath</code>	<code>false</code>	The ‘path’ (or roots or bases) of a key is the combination of key prefix, key family and macro prefix, but when dealing with ‘pathkeys’ (see section 16) the term excludes the macro prefix. These can be reserved and unreserved by any user by the tools of section 9. Subsequent users can, at their own risk, override all previously reserved paths by enabling the package’s boolean option <code>reservenopath</code> .
<code>allowemptypath</code>	<code>false</code>	Allow the use of empty key prefix and family. This isn’t advisable but some pre-existing packages might have used empty key prefixes and families. <sup>1.4</sup>
<code>pathkeys</code>	<code>false</code>	Load the <code>pathkeys</code> package (see section 16).

Table 1 notes

<sup>1.1</sup> The speed of compilation may be affected by this option, but it is recommended at the pre-production stages of developing keys. The option provide some trace functionality and enables the user to, among other things, follow the progress of the L<sup>A</sup>T<sub>E</sub>X run and to see if a key has been defined and/or set/executed more than once in the current run. The starred (\*) variants of the commands `\ltxkeys@definekeys` and `\ltxkeys@declarekeys` will always flag an error if a key is being defined twice, irrespective of the state of the package option `tracingkeys`. The `\ltxkeys@xxxkey` variants (unlike the `\ltxkeys@newxxxkey` variants) of key-defining commands don’t have this facility, and it may be desirable to know if and when an existing key is being redefined.

<sup>1.2</sup> Wherever the semicolon ‘;’ is indicated as a list parser in this guide, it can be replaced by any user-specified one character parser via the package option `keyparser`. To avoid confusing the user-supplied parser with internal parsers, it is advisable to enclose the chosen character in curly braces. The braces will be stripped off internally. Please note that some of the characters that may be passed as a list parser may indeed be active; be careful to make them innocent before using them as a list/key parser. My advice is that the user sticks with the semicolon ‘;’ as the key parser: the chances of it being made active by any package is minimal. If you have the chosen parser as literals in the callbacks of your keys, they have to be enclosed in curly braces.

<sup>1.3</sup> The key-setting commands are `\ltxkeys@setkeys`, `\ltxkeys@setrmkeys` and `\ltxkeys@setaliaskey`. If you must nest these commands beyond level 4, you have to raise the `keydepthlimit` as a package option. The option `keystacklimit` is an alias for `keydepthlimit`.

<sup>1.4</sup> The use of an empty prefix will normally result from explicitly declaring the prefix as `[]`, rather than leaving it undeclared. Undeclared prefixes assume the default value of `KV`. An empty family will result from submitting the family as empty balanced curly braces `{}`. If keys lack prefix and/or family, there is a strong risk of confusing key macros/functions. For example, without a prefix and/or family, a key named `width` will have a key macro defined as `\width`, which portents sufficient danger.

## 3 Defining keys

### 3.1 Defining only definable keys

If the package option `tracingkeys` is enabled (i.e., turned true), the user can see in the transcript file the existing keys that he has redefined with the `\ltxkeys@xxxkey` variants of the key-defining commands, which redefine existing keys without any default warning or error. The log file messages being referred to here will be highlighted with the warning sign (!!). This is always desirable in the preproduction stages of your project. However, instead of looking for these warning messages in the log file, the user can use the `\ltxkeys@newxxxkey` variants of the key-defining commands to bar himself from redefining existing keys.

Subsequently we will mention the `\ltxkeys@newxxxkey` variants of key-defining commands without necessarily explaining what they mean, since their meaning is henceforth clear.

In the following, syntactic quantities in square brackets (e.g., `[yyy]`) and those in parenthesis (e.g., `(yyy)`) are optional arguments.

### 3.2 Ordinary keys

New macros: `\ltxkeys@ordkey`, `\ltxkeys@newordkey`

```
10 \ltxkeys@ordkey[<pref>]{<fam>}{<key>}[<dft>]{<cbk>}
11 \ltxkeys@newordkey[<pref>]{<fam>}{<key>}[<dft>]{<cbk>}
```

These define a macro of the form `\<pref>@\<fam>@\<key>` of one parameter that holds the key function/callback `<cbk>`. The default value for the ‘key prefix’ `<pref>` is always `KV`, as in the `xkeyval` package. When `<key>` is used in a `\ltxkeys@setkeys` command (see section 4) containing `<key>=<value>`, the macro `\<pref>@\<fam>@\<key>` takes the value as its argument and is then executed. The given argument or key value can be accessed in the key’s callback `<cbk>` by using `#1` inside the function. The optional default value `<dft>`, if available, will be used by `\<pref>@\<fam>@\<key>` when the user hasn’t provided a value for the key at `\ltxkeys@setkeys`. If `<dft>` was absent at key definition and the key user hasn’t provided a value for the key, an error message is flagged<sup>★5</sup>.

Run the following example and do `\show\cmdb` and `\show\cmdd`:

Example: `\ltxkeys@ordkey`

```
12 \ltxkeys@ordkey[KV]{fam}{keya}[\def\cmd{#1{aa#1}}]{\def\cmdb##1{#1bb##1}}
13 \ltxkeys@ordkey[KV]{fam}{keyb}[\def\cmdc##1{cc##1}]{\def\cmdd##1{#1dd##1}}
14 \ltxkeys@setkeys[KV]{fam}{keya,keyb}
```

#### 3.2.1 Ordinary keys that share the same attributes

The commands `\ltxkeys@ordkey` and `\ltxkeys@newordkey` can be used to introduce ordinary keys `<keys>` that share the same path<sup>★6</sup> (key prefix, key family, and macro prefix) and callback `<cbk>`. All that is needed is to replace `<key>` in these commands with the comma-separated list `<keys>`. Because some users might prefer to see these commands in their plural forms when defining several keys with the same callback, we have provided the following aliases. The internal coding remains the same and no efficiency has been lost in generalization.

New macros: `\ltxkeys@ordkeys`, `\ltxkeys@newordkeys`

```
15 \ltxkeys@ordkeys[<pref>]{<fam>}{<keys>}[<dft>]{<cbk>}
16 \ltxkeys@newordkeys[<pref>]{<fam>}{<keys>}[<dft>]{<cbk>}
```

### 3.3 Command keys

New macros: `\ltxkeys@cmdkey`, `\ltxkeys@newcmdkey`

```
17 \ltxkeys@cmdkey[<pref>]{<fam>}[<mp>]{<key>}[<dft>]{<cbk>}
18 \ltxkeys@newcmdkey[<pref>]{<fam>}[<mp>]{<key>}[<dft>]{<cbk>}
```

Here, the optional quantity `<mp>` is the ‘macro prefix.’ If `<mp>` is given, the command `\<mp>\<key>` will hold the current user input at key setting time; otherwise (i.e., if `<mp>` is absent) the user input

<sup>★5</sup> The commands `\ltxkeys@key` and `\ltxkeys@newkey` aren’t user commands.

<sup>★6</sup> The key path is also called the key bases.

will be available in the macro `\cmd{pref}@{fam}@{key}`. The command `\{pref\}@{fam}@{key}` is the ‘key macro’ and will hold the callback `{cbk}`. This type of key is traditionally called ‘command key’ (a name that most likely emanated from the `xkeyval` package) because it gives rise to the macro `\{mp\}\{key\}`, but in the `ltxkeys` package even boolean, style and choice keys are associated with this type of macro.

### 3.3.1 Command keys that share the same attributes

The commands `\ltxkeys@cmdkey` and `\ltxkeys@newcmdkey` can be used to introduce command keys `{keys}` that share the same path or bases (key prefix, key family, and macro prefix) and callback `{cbk}`. Simply replace `{key}` in these commands with the comma-separated list `{keys}`. Some users might prefer to see these commands in their plural forms when defining several keys with the same callback. We have therefore provided the following aliases:

```
19   New macros: \ltxkeys@cmdkeys, \ltxkeys@newcmdkeys
20   \ltxkeys@cmdkeys[<pref>]{<fam>}[<mp>]{<keys>}[<dft>]{<cbk>}
    \ltxkeys@newcmdkeys[<pref>]{<fam>}[<mp>]{<keys>}[<dft>]{<cbk>}
```

## 3.4 Style keys

Style keys are keys with dependants (i.e., keys that are processed when the master is set). They have the following syntaxes:

```
21   New macros: \ltxkeys@stylekey, \ltxkeys@newstylekey
22   \ltxkeys@stylekey[<pref>]{<fam>}[<mp>]{<key>}[<dft>](<deps>){<cbk>}
23   \ltxkeys@stylekey★[<pref>]{<fam>}[<mp>]{<key>}[<dft>](<deps>){<cbk>}
24   \ltxkeys@newstylekey[<pref>]{<fam>}[<mp>]{<key>}[<dft>](<deps>){<cbk>}
    \ltxkeys@newstylekey★[<pref>]{<fam>}[<mp>]{<key>}[<dft>](<deps>){<cbk>}
```

The dependants `<deps>` have the syntax:

```
25   (Dependant keys syntax)
26   (
27     <keytype>/<keyname>/<dft>/<cbk>;
28     another set of dependant; etc.
   )
```

The default value `<dft>` and the callback `<cbk>` can be absent in the syntax of style keys. `<keytype>` can be ‘ord’ (ordinary key), ‘cmd’ (command key), ‘bool’ (boolean key), or ‘choice’ (choice key).

Dependant keys always share the same key prefix `<pref>`, family `<fam>`, and macro prefix `<mp>` with the parent key.

If `<mp>` is given, the command `\{mp\}\{key\}` will hold the current user input for the parent key; otherwise the user input will be available in `\style{pref}@{fam}@{key}`. The macro `\{pref\}@{fam}@{key}` will always hold the callback `<cbk>`.

If the starred (`★`) variant is used, all undefined dependants will be defined and set on the fly as the parent is being set. If the starred (`★`) variant isn’t used and undefined dependants occur, then an error message will be flagged at the time the parent is being set.

Most of the time it is possible to access the parent key’s current value with `\parentval`. Within `<dft>` and `<cbk>` of `<deps>`, it is possible to refer to the parent key’s callback with its full macro

name (i.e., `\langle pref\rangle@\langle fam\rangle@\langle key\rangle`). `\parentval` is always available for use as the default value of dependant keys, but it may be lost in the callbacks of dependant keys, because a dependant key, once defined, may be set independent of, and long after, the parent key has been executed. It is therefore more reliable to refer to the macro `\langle pref\rangle@\langle fam\rangle@\langle key\rangle@value`, which is recorded for only the parent key of style keys and which holds the current user input for the parent key. The macro `\langle pref\rangle@\langle fam\rangle@\langle key\rangle@value` is recorded only if it appears at least once in the attributes of dependant keys. The macro `\langle pref\rangle@\langle fam\rangle@\langle key\rangle@value` has a more unique name than `\langle mp\rangle\langle key\rangle` but they always contain the same value of a style key. As mentioned above, if `\langle mp\rangle` is not given, the user input for a style key will be available in the macro `\style\langle pref\rangle@\langle fam\rangle@\langle key\rangle`, instead of `\langle mp\rangle\langle key\rangle`.

**Note 3.1** ‘#1’ in the callback of parent key refers to the current value of the parent key, while ‘#1’ in the callback of any dependant key refers to the current value of that dependant key. Here is an example that defines and sets all undefined dependants on the fly:

Examples: `\ltxkeys@stylekey`

```

29 \ltxkeys@stylekey★[KV]{fam}[mp@]{keya}{[left]}]%
30   % '#1' here refers to the value of the DEPENDANT key
31   % at the time it is being set. Use \parentkey and \parentval
32   % here to access the parent key name and its current value:
33   ord/keyb/{right}/\def\y##1{##1##1};
34   % The default of keyc is the current value of parent (keya):
35   cmd/keyc/\parentval;
36   % Because \KV@fam@keya@value appears below, it will be saved
37   % when the parent key keya is being set, otherwise it would be
38   % unavailable:
39   bool/keyd/true/\ifmp@keyd\edef\x##1{##1\KV@fam@keya@value}\fi
40 ){%
41   % '#1' here refers to the value of the PARENT key at the time
42   % it is being set:
43   \def\x##1{##1xx##1xx}%
44   % Check the value of parent key:
45   \ltxkeys@checkchoice[,](\userinput\order){#1}{left,right,center}{}{%
46     @latex@error{Invalid input '#1'}\ehd
47   }%
48 }
```

In this example, `\userinput` corresponds to #1, and `\order` is the numerical order of the user input in the nominations `{left | right | center}`. More about the commands `\ltxkeys@checkchoice` and `\CheckUserInput` can be found in subsection 17.2.

You can try setting `keya` as follows to see what happens to keys `keyb`, `keyc` and `keyd`:

Example: `\ltxkeys@setkeys`

```

49 \ltxkeys@setkeys[KV]{fam}{keya=right}
```

The following will flag an error because `{right}` isn’t in the list of nominations `{left | right | center}`:

Example: `\ltxkeys@setkeys`

```

50 \ltxkeys@setkeys[KV]{fam}{keya={right}}
```

The braces in the key values above are just to exemplify the fact that braces in key values are preserved throughout key parsing. As mentioned earlier, this is essential for some packages and class files.

#### 3.4.1 Style keys that share the same attributes

The commands `\ltxkeys@stylekey` and `\ltxkeys@newstylekey` can be used to introduce style keys `<keys>` that share the same path or bases (key prefix, key family, and macro prefix) and callback `<cbk>`. Just replace `<key>` in these commands with the comma-separated list `<keys>`. However, some users might prefer to see these commands in their plural forms when defining several keys with the same callback. Hence, we also provide the following aliases:

	<b>New macros:</b> <code>\ltxkeys@stylekeys</code> , <code>\ltxkeys@newstylekeys</code>
51	<code>\ltxkeys@stylekeys[&lt;pref&gt;]{&lt;fam&gt;}[&lt;mp&gt;]{&lt;keys&gt;}[&lt;dft&gt;]{&lt;deps&gt;}{}{&lt;cbk&gt;}</code>
52	<code>\ltxkeys@stylekeys*[&lt;pref&gt;]{&lt;fam&gt;}[&lt;mp&gt;]{&lt;keys&gt;}[&lt;dft&gt;]{&lt;deps&gt;}{}{&lt;cbk&gt;}</code>
53	<code>\ltxkeys@newstylekeys[&lt;pref&gt;]{&lt;fam&gt;}[&lt;mp&gt;]{&lt;keys&gt;}[&lt;dft&gt;]{&lt;deps&gt;}{}{&lt;cbk&gt;}</code>
54	<code>\ltxkeys@newstylekeys*[&lt;pref&gt;]{&lt;fam&gt;}[&lt;mp&gt;]{&lt;keys&gt;}[&lt;dft&gt;]{&lt;deps&gt;}{}{&lt;cbk&gt;}</code>

## 3.5 Boolean keys

	<b>New macros:</b> <code>\ltxkeys@boolkey</code> , <code>\ltxkeys@newboolkey</code>
55	<code>\ltxkeys@boolkey[&lt;pref&gt;]{&lt;fam&gt;}[&lt;mp&gt;]{&lt;key&gt;}[&lt;dft&gt;]{&lt;cbk&gt;}</code>
56	<code>\ltxkeys@boolkey+*[&lt;pref&gt;]{&lt;fam&gt;}[&lt;mp&gt;]{&lt;key&gt;}[&lt;dft&gt;]{&lt;cbk&gt;}{}{&lt;fn&gt;}</code>
57	<code>\ltxkeys@newboolkey[&lt;pref&gt;]{&lt;fam&gt;}[&lt;mp&gt;]{&lt;key&gt;}[&lt;dft&gt;]{&lt;cbk&gt;}</code>
58	<code>\ltxkeys@newboolkey+*[&lt;pref&gt;]{&lt;fam&gt;}[&lt;mp&gt;]{&lt;key&gt;}[&lt;dft&gt;]{&lt;cbk&gt;}{}{&lt;fn&gt;}</code>

In these commands, if `<mp>` is given, the command `\<mp>\<key>` will hold the current user input for the key at key setting time; otherwise the user input will be available in `\bool<pref>@<fam>@<key>`<sup>7</sup>. If `<mp>` is specified, a boolean of the form `\if<mp>\<key>` will be created at key definition, which will be set by `\ltxkeys@setkeys` according to the user input. If `<mp>` is not specified, a boolean of the form `\ifbool<pref>@<fam>@<key>` will instead be created.

The user input for boolean keys must be in the set `{true | false}`. The callback `<cbk>` is held in the command `\<pref>@<fam>@<key>`, which is executed if the user input is valid.

The plus (+) variant of `\ltxkeys@boolkey` and `\ltxkeys@newboolkey` will execute `<fn>` in place of `<cbk>` if the user input isn't in `{true | false}`; the plain form will issue an error in this case.

#### 3.5.1 Boolean keys that share the same attributes

The commands `\ltxkeys@boolkey` and `\ltxkeys@newboolkey` can be used to introduce boolean keys `<keys>` that share the same path or bases (key prefix, key family, and macro prefix) and callback `<cbk>`. Just replace `<key>` in these commands with the comma-separated list `<keys>`. Because some users might prefer to see these commands in their plural forms when defining several keys with the same callback, we have provided the following aliases:

	<b>New macros:</b> <code>\ltxkeys@boolkeys</code> , <code>\ltxkeys@newboolkeys</code>
59	<code>\ltxkeys@boolkeys[&lt;pref&gt;]{&lt;fam&gt;}[&lt;mp&gt;]{&lt;keys&gt;}[&lt;dft&gt;]{&lt;cbk&gt;}</code>
60	<code>\ltxkeys@boolkeys+*[&lt;pref&gt;]{&lt;fam&gt;}[&lt;mp&gt;]{&lt;keys&gt;}[&lt;dft&gt;]{&lt;cbk&gt;}{}{&lt;fn&gt;}</code>

<sup>7</sup>This differs from the system in the `xkeyval` package.

```
61 \ltxkeys@newboolkeys[<pref>]{<fam>}[<mp>]{<keys>}[<dft>]{<cbk>}
62 \ltxkeys@newboolkeys+ [<pref>]{<fam>}[<mp>]{<keys>}[<dft>]{<cbk>}{<fn>}
```

### 3.5.2 Biboolean keys

New macros: `\ltxkeys@biboolkeys`, `\ltxkeys@newbiboolkeys`

```
63 \ltxkeys@biboolkeys[<pref>]{<fam>}[<mp>]{<bl1>,<bl2>}[<dft>]{<cbk1>}{<cbk2>}
64 \ltxkeys@biboolkeys+ [<pref>]{<fam>}[<mp>]{<bl1>,<bl2>}[<dft>]{<cbk1>}{<cbk2>}{<fn>}
65 \ltxkeys@newbiboolkeys[<pref>]{<fam>}[<mp>]{<bl1>,<bl2>}[<dft>]{<cbk1>}{<cbk2>}
66 \ltxkeys@newbiboolkeys+
67   [<pref>]{<fam>}[<mp>]{<bl1>,<bl2>}[<dft>]{<cbk1>}{<cbk2>}{<fn>}
```

Biboolean keys always assume opposite states: when one is true, the other is automatically toggled to false; and vice versa. Think of the options `draft` and `final` in a document class, but note that traditional document classes don't currently use biboolean keys. The callback `<cbk1>` belongs to the boolean key `<bl1>`, while `<cbk2>` is of `<bl2>`.

The plus (+) variant of `\ltxkeys@biboolkeys` will execute `<fn>` in place of `<cbk1>` or `<cbk2>` if the input is not in `{true | false}`; the plain form will issue an error in this case.

Biboolean keys have equal symmetry (i.e., they can call each other with equal propensity) and they won't bomb out in an infinite reentrance. They normally would know if and when they call each other, or if they're being called by some other keys.

Examples: `\ltxkeys@biboolkeys`

```
68 \ltxkeys@biboolkeys+ [KV]{fam}[mp@]{keya, keyb}[true]{%
69   \ifmp@keya\def\x##1{##1x##1}\fi
70 }{%
71   \ifmp@keyb\def\y##1{##1y##1}\fi
72 }{%
73   @latex@error{Invalid value '\string#1' for keya or keyb}\@ehc
74 }
```

### 3.6 Choice keys

The choice keys of the `ltxkeys` package differ from those of the `xkeyval` package in at least two respects; namely, the presence of the macro prefix for choice keys in the `ltxkeys` package and the introduction of the optional ‘!’ prefix.

New macros: `\ltxkeys@choicekey`, `\ltxkeys@newchoicekey`

```
75 \ltxkeys@choicekey[<pref>]{<fam>}[<mp>]{<key>}[<bin>]{<alt>}[<dft>]{<cbk>}
76 \ltxkeys@choicekey★[<pref>]{<fam>}[<mp>]{<key>}[<bin>]{<alt>}[<dft>]{<cbk>}
77 \ltxkeys@choicekey★+ [<pref>]{<fam>}[<mp>]{<key>}[<bin>]{<alt>}[<dft>]{<cbk>}{<fn>}
78 \ltxkeys@choicekey★+! [<pref>]{<fam>}[<mp>]{<key>}[<bin>]{<alt>}[<dft>]{<cbk>}{<fn>}

79 \ltxkeys@newchoicekey[<pref>]{<fam>}[<mp>]{<key>}[<bin>]{<alt>}[<dft>]{<cbk>}
80 \ltxkeys@newchoicekey★[<pref>]{<fam>}[<mp>]{<key>}[<bin>]{<alt>}[<dft>]{<cbk>}
81 \ltxkeys@newchoicekey★+
82   [<pref>]{<fam>}[<mp>]{<key>}[<bin>]{<alt>}[<dft>]{<cbk>}{<fn>}
83 \ltxkeys@newchoicekey★+!
84   [<pref>]{<fam>}[<mp>]{<key>}[<bin>]{<alt>}[<dft>]{<cbk>}{<fn>}
```

Choice keys check the user input against the nominations `<alt>` suggested by the author of a key. The comma-separated list `<alt>` is the list of admissible values of the key. The starred ( $\star$ ) variant will convert user input to lowercase before checking it against the list of nominations in `<alt>`. In all the above variants, if the input is valid, then the callback `<cbk>` will be executed. If the user input isn't valid, the non-plus variants will flag an error, while the plus (+) variants will execute `<fn>`. The ! variants will fully expand the user input before checking it against the nominations in `<alt>`. The ! variant arises from the fact that sometimes macros are passed as the values of choice keys. If `<mp>` is absent, then `\ltxkeys@choicekey` uses `\chc<pref>@<fam>@<key>` to hold the user input.

When `<alt>` has no literal form '`/.code`' or forward slash '/' in it, then it is expected to be of the familiar `xkeyval` package syntax:

```
85 {choice1,choice2,etc.} Syntax of 'nominations' for choice keys
```

If `<alt>` has '`/.code`' or '/' in it, then it is expected to have one of the following syntaxes:

```
86 {%
87   choice1/.code=callback1(keyparser)
88   choice2/.code=callback2(keyparser)
89   etc.
90 }
91 or
92 {%
93   choice1/callback1(keyparser)
94   choice2/callback2(keyparser)
95   etc.
96 }
```

If the parser is semicolon ';', then we would have

```
97 {choice1/.code=callback1; choice2/.code=callback2; etc.} Syntaxes of 'nominations' for choice keys
98 or
99 {choice1/callback1; choice2/callback2; etc.}
```

This means that if you have '`/.code`' or '/' in any of the callbacks, it has to be enclosed in curly braces! Please recall that the default value of `keyparser` is semicolon ';'. `keyparser` is a package option. This syntax also implies that if you have the `keyparser` in `<defn>`, it has to be wrapped in curly braces.

**Note 3.2** The `keyparser` in these syntaxes of 'nominations' for choice keys could also be comma ',', without the need to declare the package option `keyparser` as comma ','. Here is the rule for parsing the `<alt>` list. First the package checks if the declared key parser (i.e., `keyparser`) is in the `<alt>` list. If the parser exists in `<alt>`, then the list is parsed using this parser. Otherwise the list is parsed using comma ',' as the parser. Moreover, the package checks

if ‘`.code`’ separates `\choice` from the callback `\cbk`. If no ‘`.code`’ is found, then ‘`/`’ is assumed to be the separator. But note that when there is no `\cbk` for a nomination, then neither ‘`.code`’ nor ‘`/`’ is necessary.

It is possible to refer to the current value of `\key` as `#1` in `\alt`.

The starred (`*`) variant of `\ltxkeys@choicekey` will convert the user input to lowercase before checking `\alt` and executing the callbacks. The plus (`+`) variant will execute `\fn` in place of `\cbk` if the user input isn’t in `\alt`.

`\bin` has, e.g., the syntax `[\userinput\order]`, where `\userinput` will hold the user input (in lowercase if the starred (`*`) variant of `\ltxkeys@choicekey` is called), and `\order` will hold the serial number of the value in the list of nominations `\alt`, starting from 0. If the input isn’t valid, `\userinput` will still hold the user input, but `\order` will be `-1`.

Examples: `\ltxkeys@choicekey nominations`

```

100 \ltxkeys@choicekey[KV]{fam}{keya}{%
101   % There are no callbacks for these simple nominations:
102   center,right,left,justified
103 }[center]{% <- default value
104   \def\x##1##2{==##1##1##2==}%
105 }

106 \ltxkeys@choicekey*+[KV]{fam}[mp@]{keya}[\userinput\order]{%
107   center,right,left,justified
108 }[center]{%
109   \def\x##1##2{==##1##1##2==}%
110 }{%
111   @latex@error{Inadmissible value '\detokenize{#1}' for keya}\@ehc
112 }

113 \ltxkeys@choicekey*+[KV]{fam}[mp@]{keyb}[\userinput\order]{%
114   % There are callbacks for these nominations:
115   land/.code=\def\x##1{##1##1##1};%
116   air/.code=\edef\z{\expandonce\ltxkeys@tval};%
117   sea/.code=\edef\myinput{\cpttrimspaces{#1}};%
118   space/.code=\let\csntocs{\#1@earth}\relax
119 }[center]{%
120   \def\z##1##2{==##1##1##2==}%
121 }{%
122   @latex@error{Inadmissible value '\detokenize{#1}' for keya}\@ehc
123 }

124 \ltxkeys@choicekey[KV]{fam}[mp@]{keyb}[\userinput\order]{%
125   % The callbacks can also take the following form:
126   center/\ltxkeys@cmdkey[KV]{fam}[mp@]{keyd}{\def\x####1{####1##1####1}},%
127   right/\let\align\flushright,
128   left/\let\align\flushleft\edef\userinput{\cpttrimspaces{#1}},%
129   justified/\let\align\relax
130 }[center]{%
131   \def\z##1##2{==##1##1##2==}%
132 }

133 \ltxkeys@choicekeys[KV]{fam}[mp@]{keya,\savevalue\needvalue{keyb}}%

```

```

134 [\val\order]{%
135   center/\ltxkeys@cmdkey[KV]{fam}[mp@]{keyd}[\usevalue{keyb}]
136   {\def\x####1{####1*##1*##1}},
137   right/\def\y##1{##1++#1++##1},
138   left/\edef\userinput{\cpttrimspaces{#1}},
139   justified/\letcsntocs{#1@align}\relax
140 }[center]{%
141   \def\z##1##2{##1++#1++##2==}%
142 }
143 \ltxkeys@setkeys[KV]{fam}{keyb=center,keyd}

```

The representations `\savevalue`, `\usevalue` and `\needvalue` are pointers (see subsection 4.4).

### 3.6.1 Choice keys that share the same attributes

The commands `\ltxkeys@choicekey` and `\ltxkeys@newchoicekey` can be used to introduce choice keys `<keys>` that share the same path or bases (key prefix, key family, and macro prefix) and callback `<cbk>`. All the user has to do is to replace `<key>` in these commands with the comma-separated list `<keys>`. Some users might prefer to see these commands in their plural forms when defining several keys with the same attributes. We have therefore provided the following aliases without modifying the internal coding:

New macros: <code>\ltxkeys@choicekeys</code> , <code>\ltxkeys@newchoicekeys</code>
--

```

144 \ltxkeys@choicekeys[<pref>]{<fam>}[<mp>]{<keys>}[<bin>]{<alt>}[<dft>]{<cbk>}
145 \ltxkeys@choicekeys*[<pref>]{<fam>}[<mp>]{<keys>}[<bin>]{<alt>}[<dft>]{<cbk>}
146 \ltxkeys@choicekeys**+
147   [<pref>]{<fam>}[<mp>]{<keys>}[<bin>]{<alt>}[<dft>]{<cbk>}{<fn>}
148 \ltxkeys@choicekeys**+
149   [<pref>]{<fam>}[<mp>]{<keys>}[<bin>]{<alt>}[<dft>]{<cbk>}{<fn>}
150 \ltxkeys@newchoicekeys[<pref>]{<fam>}[<mp>]{<keys>}[<bin>]{<alt>}[<dft>]{<cbk>}
151 \ltxkeys@newchoicekeys*[<pref>]{<fam>}[<mp>]{<keys>}[<bin>]{<alt>}[<dft>]{<cbk>}
152 \ltxkeys@newchoicekeys**+
153   [<pref>]{<fam>}[<mp>]{<keys>}[<bin>]{<alt>}[<dft>]{<cbk>}{<fn>}
154 \ltxkeys@newchoicekeys**+
155   [<pref>]{<fam>}[<mp>]{<keys>}[<bin>]{<alt>}[<dft>]{<cbk>}{<fn>}

```

### 3.7 Defining boolean and command keys with one command

In my personal experience, boolean and command keys have been the most widely used types of key in the context of `xkeyval` package. More than one boolean and command keys can be defined simultaneously by the following command:

New macro: <code>\ltxkeys@definekeys</code>
---

```

156 \ltxkeys@definekeys[<pref>]{<fam>}[<mp>]{%
157   <key>=<dft>/<cbk>;
158   another set of key attributes; etc.
159 }
160 \ltxkeys@definekeys*[<pref>]{<fam>}[<mp>]{%
161   <key>=<dft>/<cbk>;
162   another set of key attributes; etc.
163 }

```

The default value `<dft>` can be absent in the case of command keys, and the callback `<cbk>` can be absent for the two types of key. Boolean keys must, however, have default values `{true | false}`, to be distinguishable from command keys. The equality sign (`=`) that separates the key name from the default value can be replaced with forward slash (/). That is, the following syntax is also permitted:

```

164  New macro: \ltxkeys@definekeys
165  \ltxkeys@definekeys[<pref>]{<fam>}[<mp>]{%
166    <key>/<dft>/<cbk>;
167    another set of key attributes; etc.
168  }
169  \ltxkeys@definekeys*[<pref>]{<fam>}[<mp>]{%
170    <key>/<dft>/<cbk>;
171    another set of key attributes; etc.
172 }
```

You can use the command `\CheckUserInput` in `<cbk>` to indirectly introduce choice keys as command keys (see example below).

Ordinary keys and conventional choice keys can't be introduced directly by this command (use the command `\ltxkeys@declarekeys` instead).

The starred (\*) variant of `\ltxkeys@definekeys` can be used to define non-existing boolean and command keys in the sense of `\newcommand`.

**Note 3.3** Keys defined by `\ltxkeys@definekeys` are automatically set-initialized instantly, to provide default values for immediate use. Boolean keys are preset with value ‘false’, so that they aren't turned ‘true’ prematurely.

**Note 3.4** In `\ltxkeys@definekeys` and `\ltxkeys@declarekeys` every line is assumed to end with a comment sign. This is to be specially noted if a space is desired at the end of line. You can insert such a space with a comment sign, or, if appropriate, use `\space`.

```

172 Examples: \ltxkeys@definekeys
173 % The starred (*) variant defines new keys:
174 \ltxkeys@definekeys*[KV]{fam}[mp@]{%
175   % Command key with callback:
176   keya={keepbraced}/\def\x##1{##1*#1*##1};
177   % Boolean key:
178   keyb=true/\def\y##1{##1yyy##1};
179   % Command key with no callback:
180   keyc=xxx;
181   % Choice-like command key:
182   keyd=center/\CheckUserInput{#1}{left,right,center}
183     \ifinputvalid
184       \edef\myval{\expandcsonce\userinput}
185       \edef\numberinlist{\number\order}
186       \edef\mychoices{\expandcsonce\nominations}
187     \else
188       \@latex@error{Input '#1' not valid}\@ehd
189     \fi;
% Boolean key with no callback:
```

```
190     keye=false;
191 }
```

In this example, `\userinput` corresponds to `#1`; `\order` is the numerical order of the user input in `\nominations`; the list of valid values suggested at key definition time (`{left | right | center}` in this example). The boolean `inputvalid` is associated with the command `\CheckUserInput` and is available to the user. It is set `true` when the user input is valid, and `false` otherwise. The command `\CheckUserInput` expects two arguments: the user input and the list of nominations. It doesn't expect two branches (see subsection 17.2).

### 3.8 Defining all types of key with one command

New macro: `\ltxkeys@declarekeys`

```
192 \ltxkeys@declarekeys[<pref>]{<fam>}[<mp>]{%
193   <keytype>/<keyname>/<dft>/<cbk>;
194   another set of key attributes;
195   etc.
196 }
197 \ltxkeys@declarekeys*[<pref>]{<fam>}[<mp>]{%
198   <keytype>/<keyname>/<dft>/<cbk>;
199   another set of key attributes;
200   etc.
201 }
```

Here, the default value `<dft>` and the callback `<cbk>` can be absent in all cases. `<keytype>` may be any one of `{ord, cmd, sty, sty*, bool, choice}`. The star (`*`) in ‘`sty*`’ has the same meaning as in `\ltxkeys@stylekey` above, namely, undefined dependants will be defined on the fly when the parent key is set. The optional quantity `<mp>` is the macro prefix, as in, e.g., subsection 3.3.

Choice keys must have their names associated with their admissible `<alt>` values in the format `<keyname>.({alt})` (see example below).

The starred (`*`) variant of `\ltxkeys@declarekeys` can be used to define new keys (in the sense of `\newcommand`).

**Note 3.5** Keys defined by `\ltxkeys@declarekeys` are automatically set instantly with their default values, to provide default functions for immediate use. Boolean keys are always initialized in this sense with ‘false’, so that they aren’t turned ‘true’ prematurely.

Examples: `\ltxkeys@declarekeys`

```
202 \ltxkeys@declarekeys*[KV]{fam}[mp@]{%
203   % Ordinary key with callback:
204   ord/keya/.1\paperwidth/\leftmargin=#1\relax;
205   % Command key with callback. ‘.code=’ is allowed before callback:
206   cmd/keyb/10mm/.code=\rightmargin=#1\def\x##1{##1*#1##1};
207   % Boolean key without callback:
208   bool/keyc/true;
209   % Boolean key with callback:
210   bool/keyd/true/\ifmp@keyd\atempswatrue\else\atempswafalse\fi;
211   % Style key with callback but no dependants:
212   sty/keye/aaa/.code=\def\y##1{##1yyy##1};
213   % Style key with callback and dependants ‘keyg’ and ‘keyh’:
214   sty*/keyf/blue/\def\y##1{##1#1}/
```

```

215     cmd>keyg>\parentval>\def\z####1{####1+##1+####1},
216     ord>keyh>\KV@fam@keyf@value;
217 % Choice key with simple nominations and callback. The function
218 % \order is generated internally:
219 choice/keyi.{left,right,center}/center/
220   \edef\shoot{\ifcase\order 0\or 1\or 2\fi};
221 % Choice key with complex nominations:
222 choice/keyj.{{
223   center/.code=\def\mp@textalign{center},
224   left/.code=\def\mp@textalign{flushleft},
225   % '.code=' can be omitted:
226   right/\def\mp@textalign{flushright},
227   justified/\let\mp@textalign\relax
228 }
229 /center/\def\yy##1{##1yy#1};
230 ord/keyk/\letcstocsn\func{as-defined-by-user}
231 }

```

Notice the `>...>` used for the attributes of the dependant keys ‘keyg’ and ‘keyh’ of style key ‘keyf’. Dependant keys come as the last attributes of a style key, and they (dependant keys) are separated by comma ‘,’. The default value of the dependant key ‘keyg’ will in this example be whatever is submitted for ‘keyf’. As indicated in subsection 3.4, the function `\KV@fam@keyf@value` has a longer shelf life than `\parentval`. Notice also the syntax `\keyi.{left,right,center}` for the choice keys ‘keyi’ and ‘keyj’. It says that the alternate admissible values for ‘keyi’ are ‘left’, ‘right’, ‘center’ and ‘justified’; similarly for key ‘keyj’.

### 3.8.1 Defining keys of common type with `\ltxkeys@declarekeys`

If you have to define keys of the same type with the command `\ltxkeys@declarekeys`, then the following syntax allows you to avoid entering the key types repeatedly:

Macro: `\ltxkeys@declarekeys`

```

232 \ltxkeys@declarekeys(<keytype>) [<pref>]{<fam>}[<mp>]{%
233   <keyname>/<dft>/<cbk>;
234   another set of key; etc.
235 }
236 \ltxkeys@declarekeys*(<keytype>) [<pref>]{<fam>}[<mp>]{%
237   <keyname>/<dft>/<cbk>;
238   another set of key; etc.
239 }

```

Examples: `\ltxkeys@declarekeys`

```

240 \ltxkeys@declarekeys(bool)[KV]{fam}[mpo]{%
241   keya/true/\def\x##1{##1*##1*##1};
242   keyb/true;
243   keyc/true/\def\y##1{##1yyy#1}
244 }
245 \ltxkeys@declarekeys*(sty*)[KV]{fam}[mpo]{%
246   keyd/xxx/\def\y##1{##1yyy#1};
247   % keyf is a dependant of keye:
248   keye/blue/\def\y##1{##1#1}/cmd>keyf>\parentval>\def\z####1{####1+##1+####1}

```

249 }

### 3.9 Need-value keys

Sometimes you may want to create keys for which the user must always supply his/her own values, even if the keys originally have default values. The default values of keys may not always be suitable. Take, for example, the height and width of a graphics image. For functions that are meant to handle generic images, it would certainly be inappropriate to relieve the user of the need to call picture height and width without corresponding values.

To make a key a need-value key, simply attach the pointer `\needvalue` to the key at definition time. This pointer can be used only when defining keys, and not when setting keys.

250	\ltxkeys@cmdkey[KV]{fam}{mp@}{\needvalue{keya}}[blue]{%
251	\def\x##1{##1x##1}%
252	}
253	\ltxkeys@setkeys[KV]{fam}{keya}
254	% -> Error: the author of ‘keya’ designed it to require a user value.

See more about key pointers in [subsection 4.4](#).

### 3.10 Cross-family keys

There are times when it is required to use the same, or nearly the same, set of keys for different functions and purposes, and thus for different key families and prefixes. We call such keys ‘cross-family keys’ or ‘xfamily keys’. Such keys bear the same names across key families and key prefixes. For example, the `xwatermark` package defines three functions (`\xwmminipage`, `\xwmbboxedminipage` and `\xwmcolorbox`) using nearly the same set of keys. In each of the three families, the keys bear the same or similar names and they have similar callbacks. The management of cross-family keys can be simplified by using the tools of this section. Even if not all the cross-family keys are needed in all the families to which they may belong, there are still advantages in using this type of keys when some of the keys cut across families.

Cross-family keys are automatically initialized after being defined—as we saw in the case of the commands `\ltxkeys@definekeys` and `\ltxkeys@declarekeys`.

255	New macros: \ltxkeys@savexfamilykeys, \ltxkeys@definexfamilykeys
256	\ltxkeys@savexfamilykeys<(id)>{(keylist)}
257	\ltxkeys@savexfamilykeys*<(id)>(keylistcmd)
258	\ltxkeys@savexfamilykeys<(id)>(<keytype>){(keylist)}
259	\ltxkeys@savexfamilykeys*<(id)>(<keytype>)(keylistcmd)
260	\ltxkeys@definexfamilykeys<(id)>[<pref>]{<fam>}[<mp>]{<na>}
	\ltxkeys@definexfamilykeys*<(id)>[<pref>]{<fam>}[<mp>]{<na>}

Here, `<id>` is the mandatory identifier of the key list `<keylist>`, `<pref>` is the key prefix, `<fam>` the key family, `<mp>` is the macro prefix, and `<na>` is the list of keys belonging to `<keylist>` that shouldn’t be presently defined and initialized. The `<na>` can be empty, but it must always be there as a mandatory argument. So, where you put the key list in the commands `\ltxkeys@definekeys` and `\ltxkeys@declarekeys` is where you now have to locate `<na>`. For any use of the command

`\ltxkeys@definexfamilykeys` we expect the `\ltxkeys@definexfamilykeys` to be far less than the remaining keys. The starred ( $\star$ ) variant of `\ltxkeys@savexfamilykeys` will expand `\keylistcmd` once before saving the xfamily keys. The starred ( $\star$ ) variant of `\ltxkeys@definexfamilykeys` will define only definable keys, in the sense of `\newcommand`.

`\keylist` and `\keylistcmd` have the same syntax as the last arguments of `\ltxkeys@definekeys` and `\ltxkeys@declarekeys`:

Syntax of keylist

```
261 <keytype>/<keyname>/<dft>/<cbk>;
262 another set of key attributes;
263 etc.
```

Here too `<keytype>` must be a member of the set `{ord, cmd, sty, sty*, bool, choice}`, `<keyname>` is obviously the name of the key, `<dft>` is the default value of the key, and `<cbk>` is the callback of the key. If the key is a style key, you can add the attributes of the dependants after `<cbk>` (see the syntaxes of the commands `\ltxkeys@definekeys` and `\ltxkeys@declarekeys`).

The mandatory identifier `<id>` for each list must be unique, notwithstanding the fact that the identifiers have their separate namespace.

If the xfamily keys are all of the same type (i.e., only one of the types `{ord, cmd, sty, sty*, bool, choice}`), you can specify `<keytype>` as an optional argument in parenthesis to the command `\ltxkeys@savexfamilykeys`. The parenthesis can't appear with an empty content.

Examples: xfamily keys

```
264 \ltxkeys@savexfamilykeys<x1>{%
265   ord/keya/\paperwidth/\mylength=#1;
266   cmd/keyb/black/\def\y##1{##1};
267   choice/keyc.{left,right,center}/center/\def\z##1{##1};
268   bool/keyd/true
269 }

270 % Now define the keys previously stored with the id no. x1.
271 % For now don't define keys keyb and keyc:
272 \ltxkeys@definexfamilykeys<x1>[KV]{fam}[mp@]{keyb,keyc}

273 % Once defined the keys can be executed separately:
274 \ltxkeys@setkeys[KV]{fam}{keya=.5\hsize, keyd=false}
275 \show\ifmp@keyd

276 % Now define the keys previously stored with the id no. x1 for
277 % another family. This time we don't want to define key keyb:
278 \ltxkeys@definexfamilykeys<x1>[KVA]{fama}[mpa@]{keyb}

279 % You can save and define xfamily keys of only one key type,
280 % command keys in the following example:
281 \ltxkeys@savexfamilykeys<x1>(cmd){%
282   keya/\paperwidth;
283   keyb/blue/\def\x##1{#1x##1};
284 }
285 % Define the saved keys and ignore none of them:
286 \ltxkeys@definexfamilykeys*<x1>[KV]{fam}[mp@]{}
```

```
287 \ltxkeys@setkeys[KV]{fam}{keya=.5\hsize,keyb=red}
```

Examples: `xfamily keys`

```
288 % 'keya' and 'keyd' are starred style keys but 'keyd' has no dependants:
289 \ltxkeys@savexfamilykeys<a1>(sty*){%
290   keya/center/.code=\def\xx##1{##1xx##1}%
291   ord>\needvalue{keyb}>\parentval>\edef\yy##1{##1yy\unexpanded{#1}}%
292   % The braces around 'center' (the default value of 'keyc')
293   % will be preserved in parsing:
294   cmd>keyc>{center};%
295   % The braces around the callback of 'keyd' will be preserved:
296   keyd/red/.code={\def\x{\color{#1}print aaa}};%
297 }
298 % Ignore 'keyd' in defining keys saved in 'a1':
299 \ltxkeys@definexfamilykeys*<a1>[KV]{fam}[mp@]{keyd}
300 % On setting 'keya', 'keyb' and 'keyc' will be defined and initialized:
301 \ltxkeys@setkeys[KV]{fam}{keya=left}
```

Here is a real-life example that mimics some of the macros of the `xwatermark` package:

Examples: `xfamily keys`

```
302 \ltxkeys@savexfamilykeys<a1>{%
303   cmd/width/\textwidth;
304   cmd/textcolor/black;
305   cmd/framecolor/black;
306   cmd/framesep/3\p@;
307   cmd/framerule/0.4\p@;
308   choice/textalign.{%
309     center/.code=\def\mp@textalign{center},
310     left/.code=\def\mp@textalign{flushleft},
311     right/.code=\def\mp@textalign{flushright}%
312   }/center;
313   bool/framebox/true;
314   ord/junkkey/throwaway;
315 }
316 % Ignore keys 'framebox' and 'junkkey' when defining family 'ltxframebox':
317 \ltxkeys@definexfamilykeys*<a1>[KV]{ltxframebox}[mp@]{framebox,junkkey}
318 % Ignore key 'junkkey' when defining family 'ltxminipage':
319 \ltxkeys@definexfamilykeys<a1>[KV]{ltxminipage}[mp@]{junkkey}
320 % No key is ignored when defining 'junkfamily':
321 \ltxkeys@definexfamilykeys<a1>[KVX]{junkfamily}[mp@]{}

322 \newcommand*\ltxframebox[2][]{%
323   \ltxkeys@setkeys[KV]{ltxframebox}{#1}%
324   \begingroup
325   \fboxsep\mp@framesep\fboxrule\mp@framerule
326   \cptdimdef\mp@boxwidth{\mp@width-2\fboxsep-2\fboxrule}%
327   \color{\mp@framecolor}%
328   \noindent
329   \fbox{%
330     \removelastskip
331     \parbox{\mp@boxwidth}{%
```

```

332     \begin{mp@textalign
333     \textcolor{\mp@textcolor}{#2}%
334     \end{mp@textalign
335   }%
336 }%
337 \endgroup
338 }
339 \newcommand*\ltxminipage[2] []{%
340   \ltxkeys@setkeys[KV]{\ltxminipage}{#1}%
341   \begingroup
342   \fboxsep\mp@framesep
343   \fboxrule\ifmp@framebox\mp@framerule\else\z@\fi
344   \cptdimdef\mp@boxwidth{\mp@width-2\fboxsep-2\fboxrule}%
345   \noindent\begin{lrbox}{\tempboxa
346   \begin{minipage}[c][\height][s]\mp@boxwidth
347   \killglue
348   \begin{mp@textalign
349   \textcolor{\mp@textcolor}{#2}%
350   \end{mp@textalign
351   \end{minipage}%
352   \end{lrbox}%
353   \killglue
354   \color{\mp@framecolor}%
355   \ifmp@framebox\fbox{\fi\usebox{\tempboxa}\ifmp@framebox}\fi
356   \endgroup
357 }

358 \begin{document}
359 \ltxframebox[
360   framecolor=blue, textcolor=purple, textalign=left
361 ]{%
362   Test text\endgraf ... \endgraf test text
363 }
364 \medskip
365 \ltxminipage[
366   framecolor=blue, textcolor=purple, framebox=true, textalign=right
367 ]{%
368   Test text\endgraf ... \endgraf test text
369 }
370 \end{document}

```

## 4 Setting keys

In the `ltxkeys` package there are many functions for setting keys. Keys can be set by the following utilities.

### 4.1 Setting defined keys

New macros: `\ltxkeys@setkeys`

```

371 \ltxkeys@setkeys[<pref>]{<fam>}[<na>]{<keyval>}
372 \ltxkeys@setkeys*{<pref>}{<fam>}[<na>]{<keyval>}

```

```
373  \ltxkeys@setkeys+[\langle prefs\rangle]{\langle fams\rangle}{\langle na\rangle}{\langle keyval\rangle}
374  \ltxkeys@setkeys★+[\langle prefs\rangle]{\langle fams\rangle}{\langle na\rangle}{\langle keyval\rangle}
```

Here, `\langle prefs\rangle`, `\langle fams\rangle` and `\langle keyval\rangle` are comma-separated list of key prefixes, families and `\langle key\rangle=\langle value\rangle` pairs, respectively. Keys listed in the comma-separated list `\langle na\rangle` are ignored. The starred ( $\star$ ) variant will save all undefined keys with prefix `\langle pref\rangle` and in family `\langle fam\rangle` in the macro `\langle pref\rangle@⟨fam⟩@⟨rmkeys⟩`, to be set later, perhaps with `\ltxkeys@setrmkeys`. The plus (+) variant will search in all the prefixes in `\langle prefs\rangle` and all families in `\langle fams\rangle` for a key before logging the key in `\langle pref\rangle@⟨fam⟩@⟨rmkeys⟩` (if the  $\star+$  variant is used) or reporting it as undefined.

To avoid infinite re-entrance of `\ltxkeys@setkeys` and the consequent bombing out of the command, the package option `keydepthlimit` is introduced. Its default value is 4, meaning that `\ltxkeys@setkeys` can't ordinarily be nested beyond level 4. If you must nest `\ltxkeys@setkeys` beyond this level, an unlikely need, you can raise the `keydepthlimit` as a package option via `\usepackage` or, if `catoptions` package is loaded before `\documentclass`, via `\documentclass`. For example,

```
375  \usepackage[keydepthlimit=6]{ltxkeys}
```

The more appropriate name `keystacklimit` is an alias for `keydepthlimit`.

## 4.2 Setting ‘remaining’ keys

The command `\ltxkeys@setrmkeys`, which has both star ( $\star$ ) and plus (+) variants, is the counterpart of `\setrmkeys` of the `xkeyval` package:

```
376  New macro: \ltxkeys@setrmkeys
377  \ltxkeys@setrmkeys[\langle pref\rangle]{\langle fam\rangle}{\langle na\rangle}
378  \ltxkeys@setrmkeys★[\langle pref\rangle]{\langle fam\rangle}{\langle na\rangle}
379  \ltxkeys@setrmkeys+[\langle prefs\rangle]{\langle fams\rangle}{\langle na\rangle}
            \ltxkeys@setrmkeys★+[\langle prefs\rangle]{\langle fams\rangle}{\langle na\rangle}
```

The command `\ltxkeys@setrmkeys` sets in the given prefixes and families the ‘remaining keys’ saved when calling the starred ( $\star$ ) variant of `\ltxkeys@setkeys` or `\ltxkeys@setrmkeys`. `\langle na\rangle` is again the list of keys that should be ignored, i. e., not executed and not saved. The unstarred variant of `\ltxkeys@setrmkeys` will report an error if a key is undefined. The starred ( $\star$ ) variant of the macro `\ltxkeys@setrmkeys`, like the starred ( $\star$ ) variant of `\ltxkeys@setkeys`, ignores keys that it cannot find and saves them on the list saved for a future call to `\ltxkeys@setrmkeys`. Keys listed in `\langle na\rangle` will be ignored fully and will not be appended to the saved list of remaining keys.

## 4.3 Setting aliased keys

Aliased keys differ from style keys of subsection 3.4. Two keys may be aliased to each other, such that when one is set, the alias is automatically set with the same or a different value. The concept is similar to, but not identical with, that of style keys. The two aliases must all be in the same family and have the same key and macro prefixes.

```
380  New macro: \ltxkeys@setaliaskey
      \ltxkeys@setaliaskey{\langle key\rangle}{\langle value\rangle}
```

Here, `<value>` is optional; if it is not given, `<key>` will be set with the current value of its alias. The command `\setaliaskey` is a shortened variant of `\ltxkeys@setaliaskey`.

Examples: `\ltxkeys@setaliaskey`

```

381 \ltxkeys@definekeys★[KV]{fam}[mp@]{%
382   printsing=true;
383   printmark=true/\ltxkeys@setaliaskey{printsing}[false];
384   keya=$+++$;
385   keyb=star/\ltxkeys@setaliaskey{keya}[$***$]
386 }
387 \ltxkeys@definekeys★[KV]{fam}[mp@]{%
388   keya=sun/\CheckUserInput{#1}{star,sun,moon}
389   \ifinputvalid
390     \edef\givenval{\userinput}
391     \edef\found{\ifcase\order star@\or sun@\or moon@\fi}
392   \else
393     @latex@error{Input '#1' not valid}\@ehd
394   \fi;
395   keyb=star/\ltxkeys@setaliaskey{keya};
396 }
```

The boolean `\ifinputvalid` associated with the command `\CheckUserInput` is described in [macro line 182](#) (see also [subsection 17.2](#)).

The example involving ‘printsign’ and ‘printmark’ is similar, but not equivalent, to the notion of biboolean keys. Biboolean keys have equal symmetry (i.e., they can call each other with equal propensity) and they won’t bomb out in an infinite reentrance. This is not the case with aliased keys: only slave/alias can set or call master/main key. If they both call each other, the user will be alerted to the fact that there is an infinite reentrance of keys. The notion of ‘slave’ and ‘master’ used in the `ltxkeys` package may be counterintuitive but in reality it is quite logical.

Schemes like the following are disallowed, to avoid back-linking of `\ltxkeys@setaliaskey`. The package will flag an error if something like the following occurs:

Examples: Illegal nested `\ltxkeys@setaliaskey`

```

397 \ltxkeys@ordkey[KV]{fam}{keya}[true]{\setaliaskey{keyb}}
398 \ltxkeys@ordkey[KV]{fam}{keyb}[true]{\setaliaskey{keya}}
399 \ltxkeys@setkeys[KV]{fam}{keya}
```

## 4.4 Using key pointers

The `\savevalue` and `\usevalue` pointers of the `xkeyval` package are still available at key setting time, but with increased robustness and optimization. Curly braces in values are preserved throughout, and instead of saving the value of each key tagged with `\savevalue` in a separate macro, we save all such keys and their values in only one macro (for each combination of `<pref>` and `<fam>`) and use a fast search technique to find the values when they are later needed (by any key tagged with `\usevalue`).

The pointer `\needvalue` is a new type. It can be used by any key author to prompt the user of the key to always supply a value for the key. The pointers `\savevalue`, `\usevalue` and `\needvalue` can all be called when defining keys. The pointer `\usevalue` will, however, be ignored when defining keys, i.e., if present, it’s simply dropped. If required at setting keys, it has to be explicitly indicated there. The pointers `\savevalue` and `\usevalue` can both be used when setting keys, but

not the pointer `\needvalue`. The presence of the pointer `\needvalue` when setting keys prompts an error.

Here is an interesting example and proof of concept of pointers:

<pre> 400 \ltxkeys@stylekeys*[KV]{fam}{% 401   \needvalue{keya},\savevalue\needvalue{keyb},\needvalue\savevalue{keyc} 402 }[[left]](% 403   % '#1' here refers to the value of the dependant key at the 404   % time it is being set. 405   ord/\savevalue{keyb}/\parentval/\edef\y##1{##1xx\unexpanded{#1}}; 406   cmd/keyc/{center} 407 ){% 408   % '#1' here refers to the value of the parent key at the time 409   % it is being set. 410   \def\x##1{##1xx#1} 411 }  412 \ltxkeys@setkeys[KV]{fam}{% 413   \savevalue{keya}={\def\y##1{##1}}, 414   \savevalue{keyb}=\usevalue{keya}, 415   keyc=\usevalue{keyb} 416 } </pre>	<span style="border: 1px solid black; padding: 2px;">Key pointers</span>
---	--

If you have to save the values of many keys, then the above scheme of placing `\savevalue` on keys at key setting time can be avoided by using the following commands:

<div style="text-align: center; margin-bottom: 5px;"> <span style="border: 1px solid black; padding: 2px;">New macros: <code>\ltxkeys@savevaluekeys</code>, <code>\ltxkeys@addsavevaluekeys</code>, etc</span> </div> <pre> 417 \ltxkeys@savevaluekeys[&lt;pref&gt;]{&lt;fam&gt;}{{&lt;list&gt;}} 418 \ltxkeys@addsavevaluekeys[&lt;pref&gt;]{&lt;fam&gt;}{{&lt;list&gt;}} 419 \ltxkeys@removesavevaluekeys[&lt;pref&gt;]{&lt;fam&gt;}{{&lt;list&gt;}} 420 \ltxkeys@undefsavevaluekeys[&lt;pref&gt;]{&lt;fam&gt;} 421 \ltxkeys@undefsavevaluekeys! [&lt;pref&gt;]{&lt;fam&gt;} 422 \ltxkeys@emptifysavevaluekeys[&lt;pref&gt;]{&lt;fam&gt;} 423 \ltxkeys@emptifysavevaluekeys! [&lt;pref&gt;]{&lt;fam&gt;} </pre>	<span style="border: 1px solid black; padding: 2px;"> </span>
---	---

The command `\ltxkeys@savevaluekeys` will create, for the given key family and prefix, a list of keys whose values should be saved at key-setting time, if those keys don't already exist in the list. The command `\ltxkeys@addsavevaluekeys` will add to the list those keys that don't already exist in the list; `\ltxkeys@removesavevaluekeys` remove those save-keys that it can find in the list; while the command `\ltxkeys@undefsavevaluekeys` will undefine the entire list of save-keys of the given key family and prefix. The command `\ltxkeys@emptifysavevaluekeys` will simplify emptify the content of the save-key list. The `!` variant of the commands

<div style="text-align: center; margin-bottom: 5px;"> <span style="border: 1px solid black; padding: 2px;">Macros</span> </div> <pre> 424 \ltxkeys@undefsavevaluekeys 425 \ltxkeys@emptifysavevaluekeys </pre>	<span style="border: 1px solid black; padding: 2px;"> </span>
--	---

will undefine or emptify the existing save-key list globally.

Examples: `\ltxkeys@savevaluekeys`

```

426 \ltxkeys@definekeys [KV]{fam}{mp@}{%
427   ord/keya/2cm/\def\x##1{#1xx##1};%
428   cmd/keyb/John;%
429   bool/keyc/true/\ifmp@keyc\def\y##1{##1yy##1}\fi;%
430   choice/keyd.{left,right,center}/%
431     \ifcase\order\def\shoot{0}\or\def\shoot{1}\or\def\shoot{2}\fi%
432   }%
433
434 \ltxkeys@savevaluekeys [KV]{fam}{keya,keyb,keyc}%
435 \ltxkeys@addsavevaluekeys [KV]{fam}{keyd}%
436 \ltxkeys@removesavevaluekeys [KV]{fam}{keya,keyb}%
437 \ltxkeys@undefsavevaluekeys [KV]{fam}%
438
439 \ltxkeys@setkeys [KV]{fam}{keya=\usevalue{keyc},keyb=\usevalue{keya}}%

```

## 4.5 Accessing the saved value of a key

As mentioned earlier, the pointers `\savevalue` and `\usevalue` are available for saving and using the values of keys within the command `\ltxkeys@setkeys`. But suppose you have used `\savevalue` within `\ltxkeys@setkeys` to set the value of a key, how do you access that value outside of `\ltxkeys@setkeys`? You can do this by using the following `\ltxkeys@storevalue` command:

New macro: `\ltxkeys@storevalue`

```

438 \ltxkeys@storevalue[<pref>]{<fam>}{<key>}{<cs>}%
439 \ltxkeys@storevalue+ [<pref>]{<fam>}{<key>}{<cs>}{<fallback>}%

```

Here, `<cs>` is the macro (defined or undefined) that will receive the saved value of `<key>`. The plain variant of this command will raise an error message if the value of the key wasn't previously saved, while the plus (+) variant will resort to the user-supplied function `<fallback>`. Only saved key values can be recovered by this command.

Examples: `\ltxkeys@storevalue`

```

440 \ltxkeys@cmdkey [KV]{fam}{\needvalue{keya}}{[<left>]}{%
441   \def\x##1{##1xx##1}%
442 }%
443 \ltxkeys@setkeys [KV]{fam}{\savevalue{keya}={\def\y##1{##1}}}%
444 \ltxkeys@storevalue [KV]{fam}{keya}\tempa%
445 \ltxkeys@storevalue+ [KV]{fam}{keya}\tempb{%
446   @latex@error{No value saved for key 'keya'}\@ehc%
447 }%

```

## 4.6 Pre-setting and post-setting keys

New macros: `\ltxkeys@presetkeys`, `\ltxkeys@postsetkeys`, etc.

```

448 \ltxkeys@presetkeys[<pref>]{<fam>}{<keys>}%
449 \ltxkeys@presetkeys! [<pref>]{<fam>}{<keys>}%
450 \ltxkeys@addpresetkeys[<pref>]{<fam>}{<keys>}%
451 \ltxkeys@addpresetkeys! [<pref>]{<fam>}{<keys>}%
452 \ltxkeys@removepresetkeys[<pref>]{<fam>}{<keys>}%

```

```

453 \ltxkeys@removepresetkeys! [{<pref>}]{<fam>}{<keys>}
454 \ltxkeys@undefpresetkeys[<pref>]{<fam>}
455 \ltxkeys@undefpresetkeys! [<pref>]{<fam>}

456 \ltxkeys@postsetkeys[<pref>]{<fam>}{<keys>}
457 \ltxkeys@postsetkeys! [<pref>]{<fam>}{<keys>}
458 \ltxkeys@addpostsetkeys[<pref>]{<fam>}{<keys>}
459 \ltxkeys@addpostsetkeys! [<pref>]{<fam>}{<keys>}
460 \ltxkeys@removepostsetkeys[<pref>]{<fam>}{<keys>}
461 \ltxkeys@removepostsetkeys! [<pref>]{<fam>}{<keys>}
462 \ltxkeys@undefpostsetkeys[<pref>]{<fam>}
463 \ltxkeys@undefpostsetkeys! [<pref>]{<fam>}
```

The optional `!` here, as in many instances in the `ltxkeys` package, means that the assignments would be done (and the lists built) globally rather than locally. ‘Presetting keys’ means ‘these keys should be set before setting other keys in every run of the command `\ltxkeys@setkeys` for the given key prefix and family’. `\ltxkeys@addpresetkeys` is an alias for `\ltxkeys@presetkeys`, and this helps explain that `\ltxkeys@presetkeys` is indeed a list merger. Neither the command `\ltxkeys@presetkeys` nor `\ltxkeys@postsetkeys` set keys itself, contrary to what the names might suggest. ‘Post-setting keys’ means ‘these keys are to be set after setting other keys in every run of `\ltxkeys@setkeys` for the given key prefix and family’. `\ltxkeys@addpostsetkeys` is an alias for `\ltxkeys@postsetkeys`. The commands

## Macros

```

464 \ltxkeys@removepresetkeys! [{<pref>}]{<fam>}{<keys>}
465 \ltxkeys@removepostsetkeys! [<pref>]{<fam>}{<keys>}
```

remove `<keys>` from preset and post-set lists, respectively. The commands

## Macros

```

466 \ltxkeys@undefpresetkeys! [{<pref>}]{<fam>}
467 \ltxkeys@undefpostsetkeys! [<pref>]{<fam>}
```

respectively, undefine all preset and post-set keys in the given family.

Logically, you can’t enter the same key twice in either preset or post-set list in the same family and prefix.

Examples: `\ltxkeys@presetkeys`, `\ltxkeys@postsetkeys`, etc.

```

468 \ltxkeys@definekeys★[KV1]{fam1}[mp@]{%
469   keya/left/\def\x##1{#1x##1};
470   \needvalue{keyb}/right;
471   keyc/center;
472   keyd
473 }
474 \ltxkeys@presetkeys! [KV1]{fam1}{keya=\flushleft,keyb=\flushright}
475 \ltxkeys@postsetkeys! [KV1]{fam1}{keyd=\flushleft}
476 ...
477 % Eventually, only ‘keya’ will be preset:
478 \ltxkeys@removepresetkeys! [KV1]{fam1}{keyb=\flushright}
479 ...
480 % Because of the ★ and + signs on \ltxkeys@setkeys, all unknown
```

```
481 % keys (those with prefix 'KV2' and in family 'fam2') will be saved in
482 % the list of remaining keys, and can be set later with \ltxkeys@setrmkeys:
483 \ltxkeys@setkeys★+ [KV1,KV2]{fam1,fam2}[keyd]{keya=xxx,keyb=yyy,keyc}
```

## 4.7 Initializing keys

New macro: `\ltxkeys@initializekeys`

```
484 \ltxkeys@initializekeys[<prefs>]{<fams>}[<na>]
```

This presets all the keys previously defined in families `<fams>` with their default values; it ignores keys listed in `<na>`. If `<na>` is a list of `<key>=<value>` pairs, the key names are extracted from the list before the family keys are initialized. Any `<key>=<value>` pairs in `<na>` are not set at all. All keys defined by `\ltxkeys@definekeys` and `\ltxkeys@declarekeys` are automatically instantly initialized, except slave/alias and dependant keys. Alias and dependant keys aren't initialized in this case in order to avoid cyclic re-entrance of `\ltxkeys@setkeys`.

The command `\ltxkeys@initializekeys` can be used in place of `\ltxkeys@executeoptions`, since `\ltxkeys@executeoptions` (similar to L<sup>A</sup>T<sub>E</sub>X kernel's `\ExecuteOptions`) fulfills the sole purpose of setting up default values of options. Keys defined via `\ltxkeys@definekeys` and `\ltxkeys@declarekeys` don't have to be initialized, since they're automatically initialized at definition time.

**Note 4.1** Keys that have been processed by `\ltxkeys@processoptions` (i.e., keys submitted by the user as package or class options via `\documentclass` or `\usepackage`) can't be initialized or launched (see subsection 4.8 below for the meaning of 'launched keys'). This is to avoid unwittingly setting keys to their default values after the user has submitted them as package or class options. This means that 'option keys' (see section 7) can't be initialized or launched.

## 4.8 Launching keys

New macro: `\ltxkeys@launchkeys`

```
485 \ltxkeys@launchkeys[<prefs>]{<fams>}{<curr>}
486 \ltxkeys@launchkeys★[<prefs>]{<fams>}{<curr>}
487 \ltxkeys@launchkeys+ [<prefs>]{<fams>}{<curr>}
488 \ltxkeys@launchkeys★+ [<prefs>]{<fams>}{<curr>}
```

This presets all keys defined in families `<fams>` with their default values; it ignores keys listed in `<curr>`. `<curr>` may be the list of `<key>=<value>` pairs that the user wants to use as current values of keys. Their keys are to be ignored when setting up defaults, i.e., when initializing the family keys. One major difference between `\ltxkeys@launchkeys` and `\ltxkeys@initializekeys` is that in `\ltxkeys@launchkeys` the `<key>=<value>` pairs in `<curr>` are immediately set after the absent family keys (i.e., those without current values) are reinitialized. Keys appearing in `<curr>` in the command `\ltxkeys@launchkeys` will be the `<na>` (ignored) keys for the command `\ltxkeys@initializekeys`.

Keys across multiple prefixes `<prefs>` and families `<fams>` can be launched at the same time, but the user has to know what is he doing: the keys might not have been defined across the given families, or some keys might have been disabled in some, and not all, families. The `*` and `+` variants of `\ltxkeys@launchkeys` have the same meaning as in `\ltxkeys@setkeys` (section 4). The starred (`*`) variant will save all undefined keys with prefix `<pref>` and in family `<fam>` in the macro `\<pref>@<fam>@<rmkeys>`, to be set later, perhaps with the command `\ltxkeys@setrmkeys`.

The plus (+) variant will search in all the prefixes in `<prefs>` and all families in `<fams>` for a key before logging the key in `\<pref>@\<fam>@\<rmkeys>` (if the `*+` variant is the one used) or reporting it as undefined.

#### 4.8.1 Non-initialize and non-launch keys

Listing all the keys that shouldn't be reinitialized by `\ltxkeys@initializekeys` in the `<na>` list every time `\ltxkeys@initializekeys` is called can sometimes be inconvenient, especially when dealing with a large number of keys. Perhaps even more important is the fact that sometimes you don't want some of the keys in a family to be reinitialized even though they are absent keys (i.e., they aren't listed as current keys, meaning that they aren't in the current `<key>= <value>` list submitted to `\ltxkeys@launchkeys`). This might be the case with package and class options. The command `\ltxkeys@nonlaunchkeys` provides a convenient means for listing the non-reinitializing keys once and for all. If there are keys in a family that shouldn't be reinitialized/launched with other keys in the same family during any call to `\ltxkeys@launchkeys` or `\ltxkeys@initializekeys`, they can be listed in the `\ltxkeys@nonlaunchkeys` command:

New macro: `\ltxkeys@nonlaunchkeys`

489 `\ltxkeys@nonlaunchkeys[<prefs>]{<fams>}{<keys>}`

Keys across multiple prefixes and families can be submitted to the `\ltxkeys@nonlaunchkeys` command: undefined keys are simply ignored by `\ltxkeys@nonlaunchkeys`.

**Note 4.2** The command `\ltxkeys@nonlaunchkeys` doesn't mean that the keys in `<keys>` can no longer be set via the command `\ltxkeys@setkeys`; it simply implies that keys appearing in `\ltxkeys@nonlaunchkeys` will not be reinitialized to their default values when members of their class are being launched or reinitialized. The command `\ltxkeys@noninitializekeys` is an alias for `\ltxkeys@nonlaunchkeys`.

#### 4.9 Handling unknown keys and options

You can use the macro `\ltxkeys@unknownkeyhandler` to declare to the `ltxkeys` package the course of action to take if, while setting keys, it discovers that a key is undefined or unknown. The command `\ltxkeys@unknownoptionhandler` applies to unknown options (see section 11)<sup>★8</sup>. The syntax of these commands is

New macros: `\ltxkeys@unknownkeyhandler`, `\ltxkeys@unknownoptionhandler`

490 `\ltxkeys@unknownkeyhandler[<prefs>]{<fams>}{<cbk>}`  
491 `\ltxkeys@unknownoptionhandler[<pref>]<>{<cbk>}`

The callback `<cbk>` signifies the action to take when an unknown key or option is encountered. The default `<cbk>` is to log the keys and, in each run, warn the user of the presence of unknown keys. The same `<cbk>` can be used across key prefixes `<prefs>` and families `<fams>`. You can use #1 (or `\CurrentPref`) in this macro to represent the current key prefix, #2 (or `\CurrentFam`) for the current family, #3 (or `\CurrentKey`) for the current key name, and #4 (or `\CurrentVal`) for the value of the current key. If `\CurrentVal` contains undefined macros or active characters, then attempting to print it may cause problems. Therefore, when making entries in the transcript file, it will sometimes be preferable to use `\InnocentVal` instead of `\CurrentVal`. However, `\InnocentVal` detokenizes the current key value and, if the value is more than 20 characters, gives only the first 20 characters of a key's value.

<sup>★8</sup> Options are also keys, but (from the user's viewpoint) there might be a need to treat options separately when dealing with unknown keys.

The following example provides an unknown key handler for two key prefixes (`KVA` and `KVB`) and two key families (`fam1` and `fam2`):

Examples: `\ltxkeys@unknownkeyhandler`

```

492 \ltxkeys@unknownkeyhandler[KVA,KVB]{fam1,fam2}{%
493   @expandtwoargs\in@{,#3,}{},\myspecialkeys,}%
494   \ifin@
495     % The reader may want to investigate what the parameter texts
496     % ##1 and #####1 below stand for (see note 4.3 below):
497     \ltxkeys@ordkey[#1]{#2}{#3}{#4}{\def\x#####1{#####1xx##1}}%
498   \else
499     \ltxmsg@warn{Unknown key '#3' with value '#4' in family '#2' ignored}@ehd
500     % \ltxmsg@warn{Unknown key '\CurrentKey' with value
501     %   '\InnocentVal' in family '\CurrentFam' ignored}@ehd
502   \fi
503 }
```

The macro `\myspecialkeys` in the above example doesn't actually exist; it is only meant for illustration here. But 'handled keys' may be introduced by the user to serve this purpose. This will be the set of keys for which special actions may apply at key setting time (see section 8).

**Note 4.3** To see what the parameter texts `##1` and `#####1` above stand for, run the following code on your own and note the outcome of `\show\KV@fam@keyd`. The characters `##1` will turn out to be the parameter text which can be used to access the current values of keys `keyd` and `keye` after they have been defined on the fly. And `#####1` will be the parameter text of the arbitrary function `\x`. If you do `\show\KV@fam@keyd`, you'll notice that the parameter texts have been reduced by one level of nesting.

Examples: `\ltxkeys@unknownkeyhandler`

```

504 \def\myspecialkeys{keyc,keyd,keye}
505 \ltxkeys@unknownkeyhandler[KV]{fam}{%
506   @expandtwoargs\in@{,#3,}{},\myspecialkeys,}%
507   \ifin@
508     \ltxkeys@ordkey[#1]{#2}{#3}{#4}{\def\x#####1{#####1xx##1}}%
509   \else
510     \ltxmsg@warn{Unknown key '#3' with value '\InnocentVal'
511       in family '#2' ignored}@ehd
512   \fi
513 }
514 \ltxkeys@setkeys[KV]{fam}{keyd=aaa,keye=bbb}
515 \show\KV@fam@keyd
```

## 5 Checking if a key is defined

New macros: `\ltxkeys@ifkeydefTF`, `\ltxkeys@ifkeydefFT`

```

516 \ltxkeys@ifkeydefTF[<prefs>]{<fams>}{{<key>}{<true>}{<false>}}
517 \ltxkeys@ifkeydefFT[<prefs>]{<fams>}{{<key>}{<false>}{<true>}}
```

These check if `<key>` is defined with a prefix in `<prefs>` and in family in `<fams>`. If the test proves that `<key>` is defined, `<true>` text will be executed; otherwise `<false>` will be executed.

## 6 Disabling keys

New macro: `\ltxkeys@disablekeys`

```
518 \ltxkeys@disablekeys[⟨prefs⟩]{⟨fams⟩}{⟨keys⟩}
519 \ltxkeys@disablekeys*[⟨prefs⟩]{⟨fams⟩}{⟨keys⟩}
```

Here, `⟨keys⟩` is a comma-separated list of keys to be disabled. The macro `\ltxkeys@disablekeys` causes an error to be issued when a disabled key is invoked. If the package option `tracingkeys` is true, undefined keys are highlighted by `\ltxkeys@disablekeys` with a warning message. Because it is possible to mix prefixes and families in `\ltxkeys@disablekeys`, undefined keys may readily be encountered when disabling keys. To see those undefined keys in the transcript file, enable the package option `tracingkeys`.

The plain form of `\ltxkeys@disablekeys` disables the given keys instantly, while the starred (\*) variant disables the keys at `\AtBeginDocument`. Authors can use this command to bar users of their keys from calling those keys after a certain point.

## 7 Option and non-option keys

Sometimes you want to create keys that can only appear in `\documentclass`, `\RequirePackage` or `\usepackage`, and at other times you may not want the user to submit a certain set of keys via these commands. The `xwatermark` package, for example, uses this concept.

New macros: `\ltxkeys@optionkeys`, `\ltxkeys@nonoptionkeys`

```
520 \ltxkeys@optionkeys[⟨pref⟩]{⟨fam⟩}{⟨keys⟩}
521 \ltxkeys@optionkeys*[⟨pref⟩]{⟨fam⟩}{⟨keys⟩}
522 \ltxkeys@nonoptionkeys[⟨pref⟩]{⟨fam⟩}{⟨keys⟩}
```

Here, `⟨keys⟩` is a comma-separated list of keys to be made option or non-option keys. Keys listed in `\ltxkeys@optionkeys` can appear only in arguments of `\documentclass`, `\RequirePackage` or `\usepackage`, while keys listed in `\ltxkeys@nonoptionkeys` can't appear in these macros. The starred (\*) variant of `\ltxkeys@optionkeys` is equivalent to `\ltxkeys@nonoptionkeys`. Only defined keys may appear in `\ltxkeys@optionkeys` and `\ltxkeys@nonoptionkeys`.

New macro: `\ltxkeys@makeoptionkeys`

```
523 \ltxkeys@makeoptionkeys[⟨pref⟩]{⟨fam⟩}
524 \ltxkeys@makeoptionkeys*[⟨pref⟩]{⟨fam⟩}
525 \ltxkeys@makenonoptionkeys[⟨pref⟩]{⟨fam⟩}
```

The command `\ltxkeys@makeoptionkeys` makes all the keys with prefix `⟨pref⟩` and in family `⟨fam⟩` options keys. The command `\ltxkeys@makenonoptionkeys` does the reverse, i.e., makes the keys non-option keys. The starred (\*) variant of `\ltxkeys@makeoptionkeys` is equivalent to `\ltxkeys@makenonoptionkeys`.

## 8 Handled keys

As mentioned in subsection 4.9, handled keys are keys defined in a macro that is key-prefix and key-family dependent. They are defined as a list in a macro so that they can be used for future applications, such as deciding if a dependant key of a style key should be defined or redefined on

the fly. Handled keys should be defined, or added to, using key prefix, family and key names. You can define or add to handled keys by the following command:

New macro: `\ltxkeys@handledkeys`

526    `\ltxkeys@handledkeys[<pref>]{<fam>}{}{<list>}`

where `<list>` is a comma-separated list of key names. This command can be issued more than once for the same key prefix `<pref>` and family `<fam>`, since the content of `<list>` is usually merged with the existing list rather than being merely added or overwritten. There is also

New macro: `\ltxkeys@addhandledkeys`

527    `\ltxkeys@addhandledkeys[<pref>]{<fam>}{}{<list>}`

which is just an alias for `\ltxkeys@handledkeys`.

Example: `\ltxkeys@handledkeys`

528    `\ltxkeys@handledkeys[KVA,KVB]{fam1,fam2}{keya,keyb,keyc}`

For a given key prefix `<pref>` and family `<fam>`, you can recall the full list of handled keys (set up earlier by `\ltxkeys@handledkeys`) by the command

List of handled keys

529    `\<pref>@<fam>@handledkeys`

You can remove handled keys from a given list of handled keys (in a family) by the following command:

New macro: `\ltxkeys@removehandledkeys`

530    `\ltxkeys@removehandledkeys[<pref>]{<fam>}{}{<list>}`

Rather than remove individual handled keys from a list, you might prefer or need to simply undefine or ‘emptyify’ the entire list of handled keys in a family. You can do these with the following commands:

New macros: `\ltxkeys@undefhandledkeys`, `\ltxkeys@emptyifyhandledkeys`

531    `\ltxkeys@undefhandledkeys[<pref>]{<fam>}`  
532    `\ltxkeys@emptyifyhandledkeys[<pref>]{<fam>}`

## 9 Reserving and unreserving key path or bases

By ‘key path’ we mean the key prefix (default is `KV`), key family (generally no default), and macro prefix (default is dependent on the type of key). However, when dealing with ‘pathkeys’ (see section 16) the term excludes the macro prefix. You can reserve key path or bases (i.e., bar future users from using the same path or bases) by the following commands. Once a key family or prefix name has been used, it might be useful barring further use of those names. For example, the `ltxkeys` package has barred users from defining keys with key family `ltxkeys` and macro prefix `ltxkeys@`.

New macros: `\ltxkeys@reservekeyprefix`, `\ltxkeys@reservekeyfamily`, etc.

```
533 \ltxkeys@reservekeyprefix{\list}
534 \ltxkeys@reservekeyprefix*{\list}
535 \ltxkeys@reservekeyfamily{\list}
536 \ltxkeys@reservekeyfamily*{\list}
537 \ltxkeys@reservemacroprefix{\list}
538 \ltxkeys@reservemacroprefix*{\list}
```

Here, `\list` is a comma-separated list of bases. The starred (`*`) variants of these commands will defer reservation to the end of the current package or class, while the unstarred variants will effect the reservation immediately. As the package or class author you may want to defer the reservation to the end of your package or class.

Users can, at their own risk, override reserved key bases simply by issuing the package boolean option `reservenopath`. This can be issued in `\documentclass`, `\usepackage` or `\ltxkeys@options`. This might be too drastic for many users and uses. Therefore, the `ltxkeys` package also provides the following commands that can be used for selectively unreserving currently reserved key bases:

New macros: `\ltxkeys@unreservekeyprefix`, `\ltxkeys@unreservekeyfamily`, etc.

```
539 \ltxkeys@unreservekeyprefix{\list}
540 \ltxkeys@unreservekeyprefix*{\list}
541 \ltxkeys@unreservekeyfamily{\list}
542 \ltxkeys@unreservekeyfamily*{\list}
543 \ltxkeys@unreservemacroprefix{\list}
544 \ltxkeys@unreservemacroprefix*{\list}
```

The starred (`*`) variants of these commands will defer action to the end of the current package or class, while the unstarred variants will undo the reservation immediately.

## 10 Bad key names

Some key names are indeed inadmissible. The `ltxkeys` considers the following literals, among others, as inadmissible for key names:

Default bad key names

<code>.code</code>	<code>ordkey</code>	<code>cmdkey</code>	<code>choicekey</code>	<code>boolkey</code>
<code>handledkeys</code>	<code>presetkeys</code>	<code>postsetkeys</code>	<code>executedkeys</code>	<code>rmkeys</code>
<code>needvalue</code>	<code>savevalue</code>	<code>usevalue</code>	<code>savevaluekeys</code>	<code>needvaluekeys</code>
<code>xkeys</code>	<code>bool</code>	<code>boolean</code>	<code>tog</code>	<code>togg</code>
<code>toggle</code>	<code>switch</code>	<code>true</code>	<code>false</code>	<code>on</code>
<code>off</code>	<code>count</code>	<code>skip</code>		

For reasons of efficiency, the `ltxkeys` package will attempt to catch bad key names only if the package option `tracingkeys` is enabled.

You can add to the list of invalid key names by the following command:

New macros: `\ltxkeys@badkeynames`, `\ltxkeys@addbadkeynames`

```
551 \ltxkeys@badkeynames{\list}
552 \ltxkeys@addbadkeynames{\list}
```

where `{list}` is a comma-separated list of inadmissible names. The updating is done by merging, so that entries are not repeated in the internal list of bad key names.

You can remove from the list of bad key names by using the following command:

553      `\ltxkeys@removebadkeynames{<list>}`

where, again, `{list}` is comma-separated. It is not advisable to remove any member of the default bad key names.

## 11 Declaring options

554      New macros: `\ltxkeys@declareoption`, `\ltxkeys@unknownoptionhandler`  
 555      `\ltxkeys@declareoption[<pref>]<>[<fam>]{<option>}[<dft>]{<cbk>}`  
 556      `\ltxkeys@declareoption*[<pref>]<>[<fam>]{<cbk>}`  
`\ltxkeys@unknownoptionhandler[<pref>]<>[<fam>]{<cbk>}`

The unstarred variant of `\ltxkeys@declareoption` is simply a form of `\ltxkeys@ordkey`, with the difference that the key family `<fam>` is now optional and, when specified, must be given in angled brackets. The default family name is ‘`\@currname.\@currext`’, i.e., the name of the class file or package and its file extension.

The starred ( $\star$ ) variant of `\ltxkeys@declareoption` prescribes the default action to be taken when undefined options with prefix `<pref>` and in family `<fam>` are passed to class or package. You may use `\CurrentKey` and `\CurrentVal` within this macro to pass the unknown option and its value to another class or package or to specify other actions. In fact, you can use `#1` in this macro to represent the current key prefix, `#2` for the current family, `#3` for the current key name, and `#4` for the value of the current key. The command `\ltxkeys@unknownoptionhandler` is equivalent to the starred ( $\star$ ) variant of `\ltxkeys@declareoption`.

**Note 11.1** The starred ( $\star$ ) variant of `\ltxkeys@declareoption` differs from the starred form of L<sup>A</sup>T<sub>E</sub>X’s `\DeclareOption` and the starred form of `xkeyval` package’s `\DeclareOptionX`.

557      Examples: `\ltxkeys@declareoption`  
 558      `\ltxkeys@declareoption*[KV]<mypackage>{%`  
 559      `\PackageWarning{mymodule}{%`  
 560      `Unknown option '\CurrentKey' with value '\InnocentVal' ignored}%`  
 561      `}`  
 562      `\ltxkeys@declareoption*{\PassOptionsToClass{#3}{article}}`  
 563      `\ltxkeys@unknownoptionhandler[KV]<mypackage>{%`  
 564      `@expandtwoargs\in@{,#3,}{},\KV@mymodule@handledkeys,}%`  
 565      `\ifin@`  
 566      `% The reader may want to investigate what the parameter texts`  
 567      `% ##1 and #####1 below stand for:`  
 568      `\ltxkeys@ordkey[#1]{#2}{#3}{#4}{\def\x#####1{#####1xx##1}}%`  
 569      `\else`  
 570      `\PassOptionsToClass{#3}{myclass}`  
 571      `\fi`  
 572      `}`

See note 4.3 for the meaning of the parameter texts in this example. The contents of the macro `\KV@mypackage@handledkeys` are handled keys for key prefix `KV` and family `fam`. See section 8 for the meaning of handled keys.

```
572     New macros: \ltxkeys@declarecmdoption, \ltxkeys@declarebooloption, etc
573     \ltxkeys@declareordoption[<pref>]<>{<option>}[<dft>]{<cbk>}
574     \ltxkeys@declarecmdoption[<pref>]<>[<mp>]{<option>}[<dft>]{<cbk>}
575     \ltxkeys@declarebooloption[<pref>]<>[<mp>]{<option>}[<dft>]{<cbk>}
576     \ltxkeys@declarechoiceoption[<pref>]{<fam>}[<mp>]{<option>}[<bin>]{<alt>}
      [<dft>]{<cbk>}
```

These are the equivalents of the macros `\ltxkeys@ordkey`, `\ltxkeys@cmdkey`, `\ltxkeys@boolkey` and `\ltxkeys@choicekey`, respectively, but now the family `<fam>` is optional (as is `<pref>`) and, when specified, must be given in angled brackets. The default family name for these new commands is '`\@currname.\@currext`', i.e., the current style or class filename and filename extension. `\ltxkeys@declareordoption` is equivalent to the unstarred variant of `\ltxkeys@declareoption`. See the choice keys in subsection 3.6 for the meaning of `<bin>` and `<alt>` associated with the command `\ltxkeys@declarechoiceoption`.

## 11.1 Options that share the same attributes

The commands

```
577     Macros
578     \ltxkeys@declareordoption
579     \ltxkeys@declarecmdoption
580     \ltxkeys@declarebooloption
      \ltxkeys@declarechoiceoption
```

can each be used to introduce several options that share the same path or bases (option prefix, option family, and macro prefix) and callback `<cbk>`. All that is needed is to replace `<option>` in these commands with the comma-separated list `<options>`. Because some users might prefer to see these commands in their plural forms when defining several options with the same callback, we have provided the following aliases.

```
581     New macros: \ltxkeys@declarecmdoptions, \ltxkeys@declarebooloptions, etc
582     \ltxkeys@declareordoptions[<pref>]<>{<option>}[<dft>]{<cbk>}
583     \ltxkeys@declarecmdoptions[<pref>]<>[<mp>]{<option>}[<dft>]{<cbk>}
584     \ltxkeys@declarebooloptions[<pref>]<>[<mp>]{<option>}[<dft>]{<cbk>}
585     \ltxkeys@declarechoiceoptions[<pref>]{<fam>}[<mp>]{<option>}[<bin>]{<alt>}
      [<dft>]{<cbk>}
```

## 11.2 Declaring all types of option with one command

```
586     New macro: \ltxkeys@declaremultitypeoptions
587     \ltxkeys@declaremultitypeoptions[<pref>]<>[<mp>]{%
588       <keytype>/<keyname>/<dft>/<cbk>;
589       another set of key attributes;
590       etc.
591     }
```

```

592   <keytype>/<keyname>/<dft>/<cbk>;
593   another set of key attributes;
594   etc.
595 }
```

Here, the key default value `<dft>` and callback `<cbk>` can be absent in all cases. `<keytype>` may be any one of `{ord, cmd, sty, sty*, bool, choice}`. The star (`*`) in ‘`sty*`’ has the same meaning as in `\ltxkeys@stylekey` above, namely, undefined dependants will be defined on the fly when the parent key is set. The optional quantity `<mp>` is the macro prefix, as in, for example, [subsection 3.3](#). The syntax for the command `\ltxkeys@declaremultypeoptions` is identical to that of `\ltxkeys@declarekeys` except for the following differences: For `\ltxkeys@declarekeys` the family is mandatory and must be given in curly braces, while for `\ltxkeys@declaremultypeoptions` the family is optional, with the default value of ‘`\@currname.\@currext`’, i.e., the name of the class file or package and its file extension. For `\ltxkeys@declaremultypeoptions`, the optional family is expected to be given in angled brackets. The starred (`*`) variant of the command `\ltxkeys@declaremultypeoptions` defines only undefined options. An alias for the long command `\ltxkeys@declaremultypeoptions` is `\declaremultypeoptions`.

Example: `\ltxkeys@declaremultypeoptions`

```

596 \declaremultypeoptions*[KV]<fam>[mp@]{%
597   cmd/option1/xx/\def\x##1{##1xx#1};%
598   bool/option2/true;%
599 }
```

## 12 Executing options

New macro: `\ltxkeys@executeoptions`

```
600 \ltxkeys@executeoptions[<prefs>]<<fams>>[<na>]{<keyval>}
```

This executes/sets the `<key>=<value>` pairs given in `<keyval>`. The optional `<na>` specifies the list of keys (without values) to be ignored. `<prefs>` is the list of prefixes for the keys; and the optional `<fams>` signifies families in which the keys suggested in `<key>=<value>` have been defined. The default value of `<fams>` is `\@currname.\@currext`. The command `\ltxkeys@executeoptions` can thus be used to process keys with different prefixes and from several families.

## 13 Processing options

New macro: `\ltxkeys@processoptions`

```

601 \ltxkeys@processoptions[<prefs>]<<fams>>[<na>]
602 \ltxkeys@processoptions*[<prefs>]<<fams>>[<na>]
```

The command `\ltxkeys@processoptions` processes the `<key>=<value>` pairs passed by the user to the class or package. The optional argument `<na>` can be used to specify keys that should be ignored. The optional argument `<fams>` can be used to specify the families that have been used to define the keys. The default value of `<fams>` is `\@currname.\@currext`. The package command `\ltxkeys@processoptions` doesn’t protect expandable macros in the user inputs unless the `ltxkeys` package is loaded before `\documentclass`, in which case it is also possible to use the

command `\XProcessOptions` of the `catoptions` package. When used in a class file, the macro `\ltxkeys@processoptions` will ignore unknown keys or options. This allows the user to use global options in the `\documentclass` command which can be inherited by packages loaded afterwards.

The starred (\*) variant of `\ltxkeys@processoptions` works like the plain variant except that, if the `ltxkeys` package is loaded after `\documentclass`, it also copies user input from the command `\documentclass`. When the user specifies an option in the `\documentclass` which also exists in the local family or families of the package issuing `\ltxkeys@processoptions*`, the local key too will be set. In this case, #1 in the command `\ltxkeys@declareoption` (or a similar command) will be the value entered in the `\documentclass` command for this key. First the global options from `\documentclass` will set local keys and afterwards the local options, specified via `\usepackage`, `\RequirePackage` or `\LoadClass`, will set local keys, which could overwrite the previously set global options, depending on the way the options sections are constructed.

### 13.1 Hooks for ‘before’ and ‘after’ processing options

New macros: `\ltxkeys@beforeprocessoptions`, `\ltxkeys@afterprocessoptions`

```
603 \ltxkeys@beforeprocessoptions{\<code>}
604 \ltxkeys@afterprocessoptions{\<code>}
```

The macros `\ltxkeys@beforeprocessoptions` and `\ltxkeys@afterprocessoptions` can be used to process an arbitrary code given in `\<code>` before and after `\ltxkeys@processoptions` has been executed. The command `\ltxkeys@afterprocessoptions` is particularly useful when it is required to optionally load a package, with the decision dependent on the state or outcome of an option in the current package. For obvious reasons, L<sup>A</sup>T<sub>E</sub>X's options parser doesn't permit the loading of packages in the options section. The command `\ltxkeys@afterprocessoptions` can be used to load packages after the current package's options have been processed. Here is an example for optionally loading some packages at the end of the options section:

Example: `\ltxkeys@afterprocessoptions`

```
605 \ltxkeys@cmdkey[KV]{fam}{mp@}{keya}[]{}%
606   \iflacus#1\dolacus\else
607     \ltxkeys@afterprocessoptions{\RequirePackage[#1]{mypackage}}%
608   \fi
609 }
```

In this example, #1 refers (as usual) to the user input for key `keya`. Here, we assume that the values of `keya` will be the `\<key>=\<value>` pairs for options of `mypackage`. The loading of `mypackage` will be determined by whether the user input for `keya` is empty or not. That is why `keya` has an empty default value. More complex application scenarios can, of course, be easily created<sup>★9</sup>.

## 14 Key commands and key environments

Key commands and environments are commands and environments that expect `\<key>=\<value>` pairs as input, in addition to any number of possible nine conventional arguments. Key commands and environments have already been introduced by the `keycommand` and `skeycommand` packages, but the inherent robustness of the `ltxkeys` provides another opportunity to re-introduce these features here. The syntax here is also simpler and the new featureset has the following advantages over those in `keycommand` and `skeycommand` packages:

<sup>★9</sup> The command `\iflacus`, whose argument is delimited by `\dolacus`, tests for emptiness of its argument.

- a) The defined commands and environments can have up to nine conventional parameters, in addition to the `\key`=`\value` pairs.
- b) Any one or all of the nine command or environment parameters can be delimited.
- c) All the various types of key (command keys, boolean keys, etc.) can be used as the keys for the new command or environment.
- d) With the prefixes `\ltxkeysglobal` and `\ltxkeysprotected`<sup>†1</sup>, global and robust key commands and environments can be defined in a manner that simulates TeX's `\global` and ε-TEx's `\protected`.
- e) The exit code for the key environment can have access to the arguments of the environment, unlike in LATEX's environment.
- f) Simple commands are provided for accessing the current values (and, in the case of boolean keys, the current states) of keys.

The specification of the mandatory arguments and any optional first argument for the key command and key environment has the same syntax as in LATEX's `\newcommand` and `\newenvironment`. The key command and key environment of the `ltxkeys` package have the syntaxes:

610	New macros: <code>\ltxkeyscmd</code> , <code>\ltxkeysenv</code> , etc
611	<code>\pref\ltxkeyscmd{cs}[\narg][\dft]&lt;\delim&gt;(\keys){\defn}</code>
612	<code>\pref\reltxkeyscmd{cs}[\narg][\dft]&lt;\delim&gt;(\keys){\defn}</code>
613	<code>\pref\ltxkeysenv{\name}[\narg][\dft]&lt;\delim&gt;(\keys){\begdefn}{\enddefn}</code>
	<code>\pref\reltxkeysenv{\name}[\narg][\dft]&lt;\delim&gt;(\keys){\begdefn}{\enddefn}</code>

Here, `\pref` is the optional command prefix, which may be either `\ltxkeysglobal` (for global commands) or `\ltxkeysprotected` (for ε-TEx protected commands); `{cs}` is the command; `{name}` is the environment name; `{narg}` is the number of parameters; `{dft}` is the default value of the first argument; `{delim}` are the parameter delimiters; `{keys}` are the keys to be defined for the command or environment; `{defn}` is the replacement text of the command; `{begdefn}` is the environment entry text; and `{enddefn}` is the code to execute while exiting the environment.

The `{keys}` have the same syntax as they do for the command `\ltxkeys@declarekeys` (subsection 3.8). The parameter delimiters `{delim}`, given above in angled brackets, have the syntax:

614	Parameter delimiters
	1 <code>\delim1</code> 2 <code>\delim2</code> ... 9 <code>\delim9</code>

where `\delim1` and `\delim2` are the delimiters for the first and second parameters, respectively, etc. Only the parameters with delimiters are to be specified in `\delim`. Examples are provided later.

In the LATEX `\newenvironment` and `\renewenvironment` commands, with the syntax

615	Macros: <code>\newenvironment</code> , <code>\renewenvironment</code>
	<code>\newenvironment{\name}[\narg][\dft]{\begdefn}{\enddefn}</code>
	<code>\renewenvironment{\name}[\narg][\dft]{\begdefn}{\enddefn}</code>

the environment's parameters and/or arguments aren't accessible in `\enddefn`. If the environment user wants to access the parameters in `\enddefn`, he has to save them while still in `\begdefn`. This isn't the case with the commands `\ltxkeysenv` and `\reltxkeysenv`, for which the user can access the environment parameters while in `\enddefn`. To do this, he should call the command

<sup>†1</sup> `\ltxkeysrobust` is an alias for `\ltxkeysprotected`.

`\envarg`, which expects as argument the corresponding numeral of the parameter text. For example, `\envarg{1}` and `\envarg{3}` refer to the first and third arguments of the environment, respectively. Examples are provided later. The current values of environment's keys can always be accessed in `\enddefn`.

But how do we access the current values or states of keys while in `\begdefn` and `\enddefn`? To this end the commands `\val`, `\ifval`, `\ifvalTF`, `\keyval`, `\ifkeyval` and `\ifkeyvalTF` are provided. They have the following syntaxes:

New macros: <code>\val</code> , <code>\ifval</code> , <code>\ifvalTF</code> , etc
---

```

617 % The following commands don't first confirm that the key exists before
618 % attempting to obtain its current value or state. They are expandable:
619 \val{<key>}
620 \ifval{<boolkey>} \then {<true>} \else {<false>} \fi
621 \ifvalTF{<boolkey>}{{<true>}}{{<false>}}
```

  

```

622 % The following commands first confirm that the key exists before attempting
623 % to obtain its current value or state. They are expandable if the key
624 % is defined:
625 \keyval{<key>}
626 \ifkeyval{<boolkey>} \then {<true>} \else {<false>} \fi
627 \ifkeyvalTF{<boolkey>}{{<true>}}{{<false>}}
```

The command `\val` yields the current value of a command or environment key, irrespective of the type of key. Its argument should exclude the key-command name, key prefix, key family, and macro prefix. The command `\ifval` expects as argument a boolean key name `<boolkey>` (without the command name, key prefix, key family, and macro prefix) and yields either `\iftrue` or `\iffalse`. The command `\ifvalTF` expects as argument a boolean key and yields one of two L<sup>A</sup>T<sub>E</sub>X branches, `<true>` or `<false>`.

The commands `\val`, `\ifval` and `\ifvalTF` can be used in expansion contexts (including in `\csname... \endcsname`) but if their arguments aren't defined as keys, they will return an undefined command, either immediately or later. On the hand, their counterparts (namely, the commands `\keyval`, `\ifkeyval` and `\ifkeyvalTF`) will first check that the key has been defined before attempting to obtain its current value or state. This affects their expandability when a key is undefined. My advice is that the user should always use `\keyval`, `\ifkeyval` and `\ifkeyvalTF` instead of `\val`, `\ifval` and `\ifvalTF`, unless he is sure he hasn't committed any mistakes in key's name; but he might be writing a package—that contains these commands—for the use of the T<sub>E</sub>X community. Also, here there is an advantage in using `\protected@edef` in place of `\edef`: some L<sup>A</sup>T<sub>E</sub>X commands are protected with `\protect`.

The commands `\val`, `\ifval`, `\ifvalTF`, `\keyval`, `\ifkeyval` and `\ifkeyvalTF`, like the command and environment keys, are available in `\defn`, `\begdefn` and `\enddefn`. These commands (i.e., `\val`, `\ifval`, `\ifvalTF`, `\keyval`, `\ifkeyval` and `\ifkeyvalTF`) are pushed on entry into `\defn` or `\begdefn`, and they are popped on exit of `\defn` or `\enddefn`. Unless they're defined elsewhere outside the `ltxkeys` package, they're undefined outside `\defn`, `\begdefn`, `\enddefn`, and the environment body<sup>‡1</sup>.

## 14.1 Final tokens of every environment

<sup>‡1</sup> The commands `\pathkeysval`, `\ifpathkeysval`, `\ifpathkeysvalTF`, `\pathkeyskeyval`, `\ifpathkeyskeyval` and `\ifpathkeyskeyvalTF` are always available, but they can be used only in the context of 'pathkeys' (section 16).

The user can add some tokens to the very end of every subsequent environment by declaring those tokens in the macro `\ltxkeys@everyeoe`, which by default contains only L<sup>A</sup>T<sub>E</sub>X's command `\ignorespacesafterend`. That is, the `ltxkeys` package automatically issues

Example: `\ltxkeys@everyeoe`

628     `\ltxkeys@everyeoe{\ignorespacesafterend}`

It is important to note that new tokens are prepended (and not appended) to the internal hook that underlies `\ltxkeys@everyeoe`, such that by default `\ignorespacesafterend` always comes last in the list. You can empty the list `\ltxkeys@everyeoe` by issuing `\ltxkeys@everyeoe{}` and rebuild it anew, still by prepending elements to it. `\ltxkeys@everyeoe` isn't actually a token list register but it behaves like one<sup>‡2</sup>. It is safe to issue `\ltxkeys@everyeoe{<token>}` and/or `\ltxkeys@everyeoe{<key>}` in the `<begdefn>` part of the key environment. One of the examples in subsection 14.2 illustrates this point.

**Note 14.1** The pointer schemes of subsection 4.4 are applicable to key commands and key environments. The `\needvalue` pointer is used in one of the examples in subsection 14.2.

## 14.2 Examples of key command and environment

Examples: Key command

```
629 % It is possible to use parameter delimiters, as the following
630 % \@nil and \@mil show:
631 % \ltxkeysglobal\ltxkeysrobust\ltxkeyscmd*\cmdframebox
632 %   [3] [default]<2@\nil 3@mil>(<keys>){<defn>}

633 % No parameter delimiters for the following:
634 \ltxkeysglobal\ltxkeysrobust\ltxkeyscmd*\cmdframebox[3] [default] (%
635   cmd/width/\textwidth;
636   cmd/textcolor/black;
637   cmd/framecolor/red;
638   cmd/framerule/.4pt;
639   cmd/framesep/4pt;
640   bool/putframe/true;
641   bool/testbool/true;
642 ){%
643   \begingroup
644   \fboxrule\keyval{framerule}\relax
645   \fboxsep\keyval{framesep}\relax
646   \ifkeyval putframe\then
647     \fcolorbox{\keyval{framecolor}}{gray!25}{%
648   \fi
649   \parbox{\keyval{width}}{%
650     \color{\keyval{textcolor}}%
651     Arg-1: #1\%
652     Arg-2: #2\%
653     Arg-3: #3%
654   }%
655   \ifkeyval putframe\then\fi
```

<sup>‡2</sup> However, you can't do `\ltxkeys@everyeoe\expandafter{\cmd}` because `\ltxkeys@everyeoe` isn't a token list register.

```

656   \ifkeyvalTF{testbool}{\def\x{T}}{\def\y{F}}%
657   \endgroup
658 }

659 \begin{document}
660 \cmdframebox[Text-1]{Text-2}\textwidth\textwidth{Text-3}{Text-4}(%
661   width=.5\textwidth,
662   framecolor=cyan,

761   textcolor=magenta,
762   putframe=true
763 )%
764 \ifval{putframe}{\then\fbox{\fi}
765 \parbox\tempb{%
766   \color{\val{textcolor}}%
767   outer box\endgraf
768   ***aaa***%
769   \vspace*{5mm}%
770   \begin{testenv}(%
771     fraclen=0.1cm,
772     framerule=3pt,
773     framecolor=green,
774     textcolor=cyan,
775     putframe=true
776   )%
777   \ifval{putframe}{\then\fbox{\fi}
778   \parbox\tempb{%
779     \color{\val{textcolor}}%
780     inner box\endgraf\vspace*{5mm}%
781     +++bbb+++
782   }%
783   \ifval{putframe}{\then\fi
784   \end{testenv}%
785 }%
786 \ifval{putframe}{\then\fi
787 \end{testenv}
788 \end{document}

```

The following example shows that in place of the functions `\val`, `\ifval`, `\ifvalTF`, `\keyval`, `\ifkeyval` and `\ifkeyvalTF` the user can access the values and states of keys by concatenating the command or environment name, the '@' sign and the name of the key. This, of course, requires that '@' has catcode 11.

Examples: Key command
-----------------------

```

789 \ltxkeyscmd\myframebox[2][default text](%
790   cmd/width/\textwidth;
791   cmd/textcolor/black;
792   cmd/framecolor/black;
793   cmd/framesep/3\p@;

```

```

794 cmd/framerule/0.4\p@;
795 % The following is choice key ‘textalign’ with default value ‘center’.
796 % The ‘.code=’ in the admissible values is optional, but not the forward
797 % slash ‘/’.
798 choice/textalign.{%
799   center/.code=\def\tttextalign{center},
800   left/.code=\def\tttextalign{flushleft},
801   right/.code=\def\tttextalign{flushright}
802 }/center;
803 bool/putframe/true
804 ){%
805   \begingroup
806   \fboxsep\myframebox@framesep
807   \fboxrule\myframebox@framerule\relax
808   \cptdimdef\myframebox@boxwidth
809   {\myframebox@width-2\fboxsep-2\fboxrule}%
810   \noindent\begin{lrbox}\@tempboxa
811   \begin{minipage}[c][\height][s]\myframebox@boxwidth
812   \@killglue
813   \begin{tttextalign}
814     \textcolor{\myframebox@textcolor}{Arg-1: #1\endgraf Arg-2: #2}%
815   \end{tttextalign}
816   \end{minipage}%
817   \end{lrbox}%
818   \@killglue
819   \color{\myframebox@framecolor}%
820   \ifmyframebox@putframe\fbox\fi
821   \usebox\@tempboxa
822   \ifmyframebox@putframe\fi
823   \endgroup
824 }

825 \begin{document}
826 \myframebox[Text-1]{Test text-2\\ ...\\test text-2}
827   (framerule=2pt,framecolor=blue,textcolor=purple,
828   putframe=true,textalign=right)
829 \end{document}

```

## 15 Declaring variables

Sometimes keys are used simply to save values for later use. This can be achieved easily by using the command `\ltxkeys@declarevariables`.

	New macro: <code>\ltxkeys@declarevariables ,\setvarvalues ,\getvarvalue</code>
--	--

```

830 \ltxkeys@declarevariables[<namespace>]{%
831   <key-1> = <dft-1> = <cbk-1>, ..., <key-n> = <dft-n> = <cbk-n>
832 }
833 \setvarvalues[<namespace>]{<key>=<value> pairs}
834 \getvarvalue[<namespace>]{<key>}

```

Here, `\key-i`, `\dft-i` and `\cbk-i` are key name, key default value, and key callback, respectively, for key ‘`i`’. The optional `\namespace` is the private namespace for the declared variables and is used to avoid clashes of control sequences.

The key default value `\dft` and callback `\cbk` are optional and may be missing in the mandatory argument of `\ltxkeys@declarevariables`.

Example: `\ltxkeys@declarevariables`

```

835 \ltxkeys@declarevariables[mynamespace]{%
836   var1 = {default value1} = \def\userinput{#1}\def\cmd##1{##1},
837   % No callback:
838   var2 = default value2,
839   % No default value and no callback:
840   var3
841 }
842 \setvarvalues[mynamespace]{var1=new value1, var2=new value2}
843 \edef\x{\getvarvalue[mynamespace]{var1}}
```

  

```

844 \begin{document}
845 \getvarvalue[mynamespace]{var1}
846 \end{document}
```

The private namespace is optional but clashes of control sequences might occur:

Example: `\ltxkeys@declarevariables`

```

847 \ltxkeys@declarevariables{%
848   var1 = {default value1} = \def\userinput{#1}\def\cmd##1{##1},
849   % No callback:
850   var2 = default value2,
851   % No default value and no callback:
852   var3
853 }
854 \setvarvalues{var1=new value1, var2=new value2}
855 \edef\x{\getvarvalue{var1}}
```

  

```

856 \begin{document}
857 \getvarvalue{var1}
858 \end{document}
```

## 16 Pathkeys

Let us start this section with a welcome message: you don’t have to repeatedly type in long key paths and commands when using pathkeys. There is plenty of help ahead on how to reduce estate when using pathkeys.

The `pathkeys` package can be loaded on its own (via `\RequirePackage` or `\usepackage`) or as an option to the `ltxkeys` package (see [Table 1](#)). All the options listed in [Table 1](#) are accepted by the `pathkeys` package. They are all passed on to `ltxkeys` package, except `pathkeys` that is simply ignored by `pathkeys` package.

Pathkeys are keys with a tree or directory structure<sup>‡3</sup>. When defining and setting pathkeys, the full key path is usually required. This is also the case when seeking the current value or state of a key. When using pathkeys the user is relieved of the need to know and remember where the optional arguments have to be placed in calls to macros. And like the commands `\ltxkeys@definekeys` and `\ltxkeys@declarekeys`, pathkeys are automatically initialized after definition, i.e., they are automatically set with their default values.

The command for defining and setting pathkeys is `\pathkeys`, which has the following syntax. The same command is used for several other tasks related to pathkeys. The ‘flag’ entry in the argument of `\pathkeys` determines the action that the command is expected to take.

859	New macros: <code>\pathkeys</code>
<code>\pathkeys{&lt;paths&gt;}/{&lt;flag&gt;} : {&lt;attrib&gt;}</code>	

In the argument of command `\pathkeys`, `<paths>` has the syntax

860	New macros: <code>\pathkeys</code>
<code>&lt;main1&gt;/&lt;sub1&gt;/&lt;subsub1&gt;/..., &lt;main2&gt;/&lt;sub2&gt;/&lt;subsub2&gt;/..., etc.</code>	

in which individual paths are separated by comma ‘,’. The quantity `<main>` is the main path and `<sub>` is the sub path, etc. Note that there is no forward slash (`/`) before `<paths>` or `<main>`. If the path is empty, the default path ‘`dft@main/dft@sub/`’, or the user-supplied current path (see later), is used. There is more about the default and current paths later in this guide.

The `<attrib>` is determined by the key called `<flag>`. The `<flag>` determines the action the command `\pathkeys` takes, and must be a member of the set described in [Table 2](#). The action specified by `<flag>` is, if applicable on all the given paths, taken on all the given paths<sup>‡4</sup>. See the table notes for the `<attrib>`’s of the flags. The attributes describe the arguments associated with the flags, i.e., the quantities expected after the colon ‘:’ in the argument of `\pathkeys`. The `<na>` is the list of keys that are ignored by the `<flag>`’s action. If it is present in the attribute `<attrib>` part of `\pathkeys`, it must always be given in square brackets ‘`[]`’ (see [note 16.1](#)).

For flags with `*` and `+` signs the user should make sure there is no space between the flag and its star or plus sign: such a space will not be zapped internally, since syntactic matching is required.

Table 2: Flags and attributes for pathkeys

No.	Flag	Meaning
1	<code>define</code>	Define the keys whether or not they already exist. <small>See note 2.1</small>
2	<code>define*</code>	Define the keys only if they don’t already exist. <small>2.2</small>
3	<code>declareoptions</code>	Declare the given options whether or not they already exist. <small>2.3</small>
4	<code>declareoptions*</code>	Declare the options if they don’t already exist. <small>2.4</small>
5	<code>preset</code>	Preset the listed keys on the given path. This actually means preparing the list of preset keys. <small>2.5</small>
6	<code>preset!</code>	Preset the listed keys, saving the list globally. <small>2.6</small>
7	<code>postset</code>	Post-set the listed keys. <small>2.7</small>
8	<code>postset!</code>	Post-set the listed keys, saving the list globally. <small>2.8</small>

*Continued on next page*

<sup>‡3</sup> This might sound like `pgf` keys, but the semantics, syntaxes, and the implementation here are all different from those of `pgf` keys.

<sup>‡4</sup> However, in most of this manual only one path is used in the sample syntaxes and in the examples.

<i>Continued from last page</i>		
No.	Flag	Meaning
9	<code>set</code>	Set the listed keys. <sup>2.9</sup>
10	<code>set*</code>	Set the listed keys and save undefined keys in the list of ‘remaining keys’ without raising errors. <sup>2.10</sup>
11	<code>set*+</code>	Set the listed keys in all the given key prefixes and families; save undefined keys in the list of ‘remaining keys’ without raising errors. <sup>2.11</sup>
12	<code>setrm</code>	Set the ‘remaining keys’. <sup>2.12</sup>
13	<code>setrm*</code>	Set the ‘remaining keys’ and again save undefined keys in the revised list of ‘remaining keys’ without raising errors. <sup>2.13</sup>
14	<code>setrm*+</code>	Set the ‘remaining keys’ in all the given key prefixes and families; save undefined keys in the revised list of ‘remaining keys’ without raising errors. <sup>2.14</sup>
15	<code>executeoptions</code>	Execute the listed options. <sup>2.15</sup>
16	<code>processoptions</code>	Process the listed options in the order in which they were declared, and don’t copy <code>\documentclass</code> options. <sup>2.16</sup>
17	<code>processoptions*</code>	Process the listed options in the order in which they appear in the command <code>\usepackage</code> , and copy <code>\documentclass</code> options. <sup>2.17</sup>
18	<code>launch</code>	Launch the listed keys (see subsection 4.8). <sup>2.18</sup>
19	<code>store value</code>	Store the value of <code>&lt;key&gt;</code> in the given <code>&lt;macro&gt;</code> . <sup>2.19</sup>
20	<code>print value</code>	Print the current value of <code>&lt;key&gt;</code> . <sup>2.20</sup>
21	<code>add value</code>	Add the specified value to the current value of key. <sup>2.21</sup>
22	<code>ifbool</code>	Test the state of a boolean key. This returns <code>&lt;true&gt;</code> or <code>&lt;false&gt;</code> . <sup>2.22</sup>
23	<code>ifdef</code>	Test if key is currently defined on any of the given comma-separated multiple paths. This returns <code>&lt;true&gt;</code> or <code>&lt;false&gt;</code> . <sup>2.23</sup>
24	<code>ifkeyonpath</code>	Test if key is currently defined on any of the given comma-separated multiple paths. This returns <code>&lt;true&gt;</code> or <code>&lt;false&gt;</code> . <sup>2.24</sup>
25	<code>disable</code>	Immediately disable the given keys. <sup>2.25</sup>
26	<code>disable*</code>	Disable the given keys at the hook <code>\AtBeginDocument</code> and not immediately. <sup>2.26</sup>
27	<code>key handler</code> or <code>handler</code>	Unknown key handler. <sup>2.27</sup>
28	<code>option handler</code>	Unknown option handler (see subsection 4.9). Options are keys with a special default family. There might be a reason to handle unknown options separately from unknown keys.

**Table 2 notes**

These notes describe the attributes of handlers, i.e., what are required to be specified in the command `\pathkeys` after the colon ‘:’ sign. `<na>` keys are the keys to be ignored; they must appear in square brackets, e.g., `[keya]`.

<sup>2.1</sup> See attribute in note 16.1.

<sup>2.2</sup> Same as for `define` flag.

<sup>2.3</sup> Same as for `define` flag.

<sup>2.4</sup> The flag `declareoptions*` simply signifies the user’s aim to define definable options; it has nothing to do with the starred (\*) variant of the command `\ltxkeys@declareoption` of section 11. The attribute is the same as for `define` flag.

<sup>2.5</sup> `<key>=<value>` pairs (see subsection 4.6).

<sup>2.6</sup> `<key>=<value>` pairs (see subsection 4.6).

<sup>2.7</sup> `<key>=<value>` pairs (see subsection 4.6).

<sup>2.8</sup> `<key>=<value>` pairs (see subsection 4.6).

- <sup>2.9</sup> `{na}` keys and `{key}={value}` pairs (see section 4).
- <sup>2.10</sup> `{na}` keys and `{key}={value}` pairs (see section 4).
- <sup>2.11</sup> `{na}` keys and `{key}={value}` pairs (see section 4).
- <sup>2.12</sup> `{na}` keys (see subsection 4.2).
- <sup>2.13</sup> `{na}` keys (see subsection 4.2).
- <sup>2.14</sup> `{na}` keys (see subsection 4.2).
- <sup>2.15</sup> `{na}` keys and `{key}={value}` pairs (see section 12).
- <sup>2.16</sup> `{na}` keys (see section 13).
- <sup>2.17</sup> `{na}` keys (see section 13).
- <sup>2.18</sup> `{key}={value}` pairs.
- <sup>2.19</sup> `{key}` and `{macro}`, e.g., `keya \cmda`.
- <sup>2.20</sup> `{key}`, e.g., `keya`.
- <sup>2.21</sup> `{key}` and `{value}`.
- <sup>2.22</sup> `{key}`.
- <sup>2.23</sup> `{key}`.
- <sup>2.24</sup> `{key}`.
- <sup>2.25</sup> The attribute is a comma-separated key list.
- <sup>2.26</sup> Comma-separated key list.
- <sup>2.27</sup> The arguments of the unknown key or option handler are the main path, subpaths (separated by forward slash), key name, and the current key value (see subsection 4.9). The key or option handler can have up to a maximum of 4 arguments.

**Note 16.1** The syntax for specifying keys to be defined by `\pathkeys` is (see subsection 3.8)

Syntax for defining keys in `\pathkeys`

```

861 \pathkeys{<path>}{define:
862   <keytype>/<keyname>/<dft>/<cbk>;
863   another set of key attributes;
864   etc.
865 }
```

The default value `<dft>` and the callback `<cbk>` can be absent in all cases. `<keytype>` may be any member of the set `{ord, cmd, sty, sty*, bool, choice}`. The star ( $\star$ ) in ‘`sty $\star$` ’ has the same meaning as in `\ltxkeys@stylekey` (subsection 3.4), namely, undefined dependants will be defined on the fly when the parent is set/executed.

Example: Syntax for defining pathkeys

```

866 % Define keys on only one path:
867 \pathkeys{fam/subfam/subsubfam}{define:
868   cmd/keya/defaultval/\def\cmda#1{#1};
869   bool/keyb/true;
870 }
871 % Define keys on multiple paths:
872 \pathkeys{fam1/subfam1/subsubfam1,fam2/subfam2/subsubfam2,...}{define:
873   cmd/keya/defaultval/\def\cmda#1{#1};
874   bool/keyb/true;
875 }
```

Choice keys must have their names associated with their nominations (i.e., admissible values) in the format `<keyname>.<{nominations}>`, as below (see also [subsection 3.8](#)):

Syntax for defining choice keys in `\pathkeys`

```

876 % 'keya' is a choice key with simple nominations and callback, while 'keyb'
877 % is a choice key with complex nominations. The function \order is generated
878 % internally by the package for choice keys.
879 \pathkeys{fam/subfam/subsubfam/define:
880   choice/keya.{left,right,center}/center/
881     \edef\x{\ifcase\order 0\or 1\or 2\fi};
882   choice/keyb.{%
883     center/.code=\def\textalign{center},
884     left/.code=\def\textalign{flushleft},
885     % '.code=' can be omitted, as in:
886     right/\def\textalign{flushright},
887     justified/\let\textalign\relax
888   }/center/\def\x##1{##1xx##1};
889 }
```

The `<na>` keys, if they are present in the attribute of `\pathkeys`, must always be given in square brackets `[]`. They can come either before or after the `<key>=<value>` list to be set in the current run. For example,

Example: 'na' keys

```

890 \pathkeys{fam/subfam/subsubfam/define:
891   cmd/keya/xx/\def\cmda#1{#1};
892   bool/keyb/true;
893 }
894 % Set 'keya' and ignore 'keyb':
895 \pathkeys{fam/subfam/subsubfam/set: keya=zz,keyb=true [keyb]}
896 % or
897 \pathkeys{fam/subfam/subsubfam/set: [keyb] keya=zz,keyb=true}
```

See [subsection 16.4](#) for further examples of the use of ignored keys. Here we can see that a value is provided for 'keyb' and yet we're ignoring the key. However, in practical applications it is often impossible to predict the set of keys (among a set of them) that may be executed at any time by the user of the keys. Therefore, `<na>` keys are much more useful than the above example demonstrates•

Some of the commands associated with pathkeys are listed below. The abbreviation `<pk>` means the full key path and key name, all separated by forward slash.

New macros: `\pathkeysval`, `\ifpathkeysval`, `\ifpathkeysvalTF`, etc.

```

898 % The following commands are expandable:
899 \pathkeysval{<pk>}
900 \ifpathkeysval{<pk>} \then ... \else ... \fi
901 \ifpathkeysvalTF{<pk>}{<true>}{<false>}
902 % The following commands aren't expandable:
903 \pathkeyskeyval{<pk>}
904 \ifpathkeyskeyval{<pk>} \then ... \else ... \fi
905 \ifpathkeyskeyvalTF{<pk>}{<true>}{<false>}
906 \pathkeys@storevalue{<pk>}{cmd}
```

The commands `\pathkeysval` and `\pathkeyskeyval` simply yield the current value of the key. The commands `\ifpathkeysval` and `\ifpathkeyskeyval`, which require `\then` to form balanced conditionals, test the current state of the boolean key `\pk` in a TeX-like syntax. The commands `\ifpathkeysvalTF` and `\ifpathkeyskeyvalTF` also test the current state of the boolean key `\pk` but return `\true` or `\false` in a L<sup>A</sup>T<sub>E</sub>X syntax. The command `\pathkeys@storevalue` stores the current value of key `\pk` in the given command `\cmd`.

**Note 16.2** If called outside an assignment or document environment, the macros `\pathkeysval` and `\pathkeyskeyval` can give ‘no document error’, to signify that a token has been output outside these situations. And one source of problem with `\ifpathkeysval` and `\ifpathkeyskeyval` is to omit `\then` after their argument. If you find yourself typing long key paths and the commands `\pathkeysval` and `\pathkeyskeyval`, etc., repeatedly, there is help ahead on how to reduce estate when using pathkeys.

The following provide our first examples of pathkeys and a demonstration of some of the commands associated with pathkeys.

Examples: Pathkeys

```

907 \pathkeys{fam/subfam/subsubfam/define:
908   cmd/xwidth/\@tempdima/\def\y##1{#1yy##1};
909   cmd/keya/\def\cmda#1{#1};
910   bool/putframe/true;
911 }
912 \pathkeys{fam/subfam/subsubfam/set: putframe=true [keya]}
913 \pathkeys{fam/subfam/subsubfam/ifdef: xwidth}{\def\x{T}}{\def\x{F}}
914 \pathkeys{fam/subfam/subsubfam,famx/subfamx/subsubfamx/ifkeyonpath: xwidth}
915   {\def\x{T}}{\def\x{F}}
916 \pathkeys{fam/subfam/subsubfam/print value: xwidth}=\z@pt
917 \pathkeys{fam/subfam/subsubfam/store value: keya \cmd}
918 \pathkeys{fam/subfam/subsubfam/add value: keya=\def\cmdb#1{#1}}
919 \pathkeys@storevalue{fam/subfam/subsubfam/putframe}\cmd
920 \edef\x{\ifpathkeysvalTF{fam/subfam/subsubfam/putframe}{T}{F}}
921 \edef\x{\ifpathkeysval fam/subfam/subsubfam/putframe\then T\else F\fi}
922 \edef\x{\ifpathkeysval fam/subfam/subsubfam/putframe\then T\else F\fi}
923 % 'xputframe' is undefined. What does the following return?
924 \edef\x{\pathkeysval{fam/subfam/subsubfam/xputframe}}
925 % Unknown key handler:
926 \pathkeys{fam/subfam/subsubfam/key handler:
927   % '#1' is the key's main path, '#2' is the subpaths combined,
928   % '#3' is the key name, and '#4' is the current value of the key:
929   \ltxkeys@warn{Unknown key '#3' with value '#4' ignored.}%
930 }
931 \pathkeys{fam/subfam/subsubfam/disable*: keya,keyb,keyc}
```

Examples: Pathkeys

```

932 \pathkeys{KV/frame/framebox/define*:
933   cmd/width/\textwidth/\def\x##1{#1xx##1};
934   cmd/textcolor/black;
935   cmd/framecolor/black;
936   cmd/framesep/3\p@;
937   cmd/framerule/0.4\p@;
938   cmd/cornersize/20\p@;
939   choice/textalign.{%
```

```

940     center/.code=\def\tttextalign{center},
941     left/.code=\def\tttextalign{flushleft},
942     right/.code=\def\tttextalign{flushright}
943   }/center;
944   bool/putframe/true;
945   cmd/arga;
946   cmd/argb;
947 }

948 \newcommand*\myframebox[1][]{%
949 % Use 'set' or 'launch' here, but they don't have the same meaning:
950   \pathkeys{KV/frame/framebox/set:#1}%
951   \begingroup
952   \fboxsep\pathkeysval{KV/frame/framebox/framesep}%
953   \fboxrule\pathkeysval{KV/frame/framebox/framerule}\relax
954   \cptdimdef\boxwidtha{%
955     \pathkeysval{KV/frame/framebox/width}-2\fboxsep-2\fboxrule
956   }%
957   \noindent\begin{lrbox}\@tempboxa
958   \begin{minipage}[c][\height][s]\boxwidtha
959   \@killglue
960   \begin{tttextalign}
961     \textcolor{\pathkeysval{KV/frame/framebox/textcolor}}{%
962       Arg-1: \pathkeysval{KV/frame/framebox/arga}}
963       \endgraf
964       Arg-2: \pathkeysval{KV/frame/framebox/argb}%
965     }%
966   \end{tttextalign}
967   \end{minipage}%
968   \end{lrbox}%
969   \@killglue
970   \color{\pathkeysval{KV/frame/framebox/framecolor}}%
971   \ifpathkeysval{KV/frame/framebox/putframe}\then\ovalbox{\fi
972     \usebox\@tempboxa
973   \ifpathkeysval{KV/frame/framebox/putframe}\then}\fi
974   \endgroup
975 }

976 \begin{document}
977 \myframebox[arga=Text-1,argb={Test text-2\\ ...\\test text-2},
978   framerule=2pt,framecolor=blue,textcolor=purple,
979   putframe=true,ttalign=right]
980 \end{document}

```

**Note 16.3** When using pathkeys (and in general the commands `\ltxkeys@definekeys` and `\ltxkeys@declarekeys`), there is a potential problem in deploying forward slashes in key defaults and macros without enclosing those slashes in curly braces. They will confuse the parser. Several solutions exist, including tweaking the relevant internal parser, but I haven't decided on the optimal solution to this possibility. For example, the following will fail:

Example: Forward slashes in key defaults and macros

```

981 \pathkeys{fam/subfam/subsubfam/define*:
982   bool/keya/true/\ifpathkeysval fam/subfam/subsubfam/keya\then
983     \def\x{T}\else\def\x{F}\fi;
984 }
```

Its correct form is

Example: Forward slashes in key defaults and macros

```

985 \pathkeys{fam/subfam/subsubfam/define*:
986   bool/keya/true/\ifpathkeysval{fam/subfam/subsubfam/keya}\then
987     \def\x{T}\else\def\x{F}\fi;
988 }
```

## 16.1 Shortened pathkeys commands

As seen above, the estate for deploying pathkeys can be large when compared with the amount of typing required for conventional keys presented in the previous chapters. To reduce the estate, the first line of thought is to store any long path in a macro and call the macro instead of the path. The path is always fully expanded under safe actives. The following example demonstrates this approach.

Examples: Putting paths in macros

```

989 \def\mypath{fam/subfam/subsubfam}
990 \pathkeys{\mypath/define:
991   cmd/xwidth/@tempdima/\def\y##1{#1yy##1};
992   cmd/keya/\def\cmd{#1{#1};
993   bool/putframe/true
994 }
995 \pathkeys{famx/subfamx,fam/subfam/ifkeyonpath: xwidth}{\def\x{T}}{\def\x{F}}
996 \pathkeys{famx/subfamx,\mypath/ifkeyonpath: xwidth}{\def\x{T}}{\def\x{F}}
997 \pathkeys{\mypath/set: putframe=true}
998 \pathkeys{\mypath/ifdef: xwidth}{\def\x{T}}{\def\x{F}}
999 \pathkeys{\mypath/print value: xwidth}=\z@pt
1000 \pathkeys@storevalue{\mypath/putframe}\cmd
1001 \edef\x{\ifpathkeysvalTF{\mypath/putframe}{T}{F}}
1002 \edef\x{\ifpathkeysval {\mypath/putframe}\then T\else F\fi}
1003 \edef\x{\ifpathkeysval {\mypath/putframe}\then T\else F\fi}
1004 \pathkeys{\mypath/add value: keya=\def\cmd{#1}}
```

Instead of defining your own commands like the above `\mypath`, you can use the following name-spaced commands:

New macros: `\newpath`, `\defpath`, `\changePath`, `\undefpath`, `\usepath`

```

1005 \newpath{<pathname>}{<path>}
1006 \defpath{<pathname>}{<path>}
1007 \changePath{<pathname>}{<path>}
1008 \undefpath{<pathname>}
1009 \usepath{<pathname>}
```

These commands have their own separate namespace. Here, `\<pathname>` is used, after definition, as an abbreviation for the full path `\<path>`. The command `\newpath` creates `\<pathname>` if it didn't already exist; `\defpath` creates `\<pathname>` whether or not it exists; `\changePath` is equivalent to `\defpath`; `\undefpath` undefines `\<pathname>`; and `\usepath` expands `\<pathname>` to its full meaning. The macro `\usepath` does accept, as argument, a comma-separated list of pathnames. When using the flag `ifdef` or `ifkeyonpath`, if `\<path>` or `\<pathname>` is a comma-separated list, all the given paths are searched in determining if the key is defined (see the following example).

Examples: `\newpath`, `\usepath`

```

1010 \newpath{path1}{fam/subfam/subsubfam1}
1011 \newpath{path2}{fam/subfam/subsubfam2}
1012 \pathkeys{\usepath{path1}/define:
1013   cmd/keya/xx/\def\cmda#1{#1};
1014   bool/keyb/true
1015 }
1016 \pathkeys{\usepath{path1, path2}/ifkeyonpath: keya}{\def\x{T}}{\def\x{F}}
1017 \pathkeys@storevalue{\usepath{path1}/keyb}\cmd
1018 \edef\x{\ifpathkeysvalTF{\usepath{path1}/keya}{T}{F}}
```

Examples: `\defpath`, `\usepath`, `set`, `setrm`

```

1019 \defpath{path1}{fam/subfam/subsubfam1}
1020 \defpath{path2}{fam/subfam/subsubfam2}
1021 % Define 'key1' on two paths:
1022 \pathkeys{\usepath{path1, path2}/define*:
1023   cmd/key1/12cm/\def\y##1{#1yy##1}
1024 }
1025 % Set keys on paths 1 and 2 and put undefined keys in the 'rm list'
1026 % instead of raising errors:
1027 \pathkeys{\usepath{path1, path2}/set**:
1028   key1=10cm, key2=true, key3=xx
1029 }
1030 % Set 'rm keys' and again put undefined keys in the 'rm list'
1031 % instead of raising errors:
1032 \pathkeys{\usepath{path1, path2}/setrm**:}
```

The following shortened counterparts of the `pathkeys` commands are provided (see [Table 3](#)). The abbreviated commands are available only after the user has invoked `\pathkeys@useshortcmds`, which expects no argument. The command `\pathkeys@useshortcmds` has only local effect, i.e., the abbreviations may be localized to a group. The abbreviations are defined only if they're definable (i.e., didn't exist before calling the command `\pathkeys@useshortcmds`).

Table 3: Pathkeys command abbreviations

Command	Abbreviation	Command	Abbreviation
<code>\pathkeysval</code>	<code>\pkv</code>	<code>\pathkeyskeyval</code>	<code>\pkvv</code>
<code>\ifpathkeysval</code>	<code>\ifpkv</code>	<code>\ifpathkeyskeyval</code>	<code>\ifpkvv</code>
<code>\ifpathkeysvalTF</code>	<code>\ifpkvTF</code>	<code>\ifpathkeyskeyvalTF</code>	<code>\ifpkvvTF</code>

The user isn't constrained to use the short form commands of [Table 3](#). He/she can define his/her own short forms by using the command `\pathkeys@makeshortcmds`, which has the syntax:

1033                    New macro: `\pathkeys@makeshortcmds`

```
\pathkeys@makeshortcmds{\<short-1>=\<long-1>, ..., \<short-n>=\<long-n>}
```

where `\<short-i>` and `\<long-i>` are the short (new) and long (existing) aliases of the command `\i`. The equality sign (`=`) is mandatory here. You don't have to (in fact, you shouldn't) call `\pathkeys@useshortcmds` after calling `\pathkeys@makeshortcmds`.

1034                    Example: `\pathkeys@makeshortcmds`

```
\pathkeys@makeshortcmds{\kval=\pathkeyskeyval,\ifkvalTF=\ifpathkeyskeyvalTF}
```

## 16.2 Default and current paths

1035                    New macros: `\pathkeys@currentpath`, etc.

```
\pathkeys@addtodefaultpath{\<path>}
\pathkeys@changedefaultpath{\<path>}
\pathkeys@currentpath{\<path>}
\pathkeys@usedefaultpath
\pathkeys@pushcurrentpath
\pathkeys@popcurrentpath
\pathkeys@pathhistory
```

If the key path is empty, then the current path will be used; and if there is no current path, the default path will be used. The default path is `dft@main/dft@sub`. This can be changed by the commands `\pathkeys@addtodefaultpath` and `\pathkeys@changedefaultpath`. The current path can be declared by providing an argument to the command `\pathkeys@currentpath`. The default path can be made the current path by invoking the command `\pathkeys@usedefaultpath`, which is parameterless.

It isn't mandatory, but it is useful, to first push the prevailing path before changing it. This can be done by calling the parameterless command `\pathkeys@pushcurrentpath`. When you're done with the current path, you can revert to the path before the current path by calling the command `\pathkeys@popcurrentpath`. You can get the entire history of path changes from the container `\pathkeys@pathhistory`, which is useful in complex situations. However, it should be noted that `\pathkeys@pathhistory` doesn't contain a chronological order of path changes: if a path is already contained in it, it wouldn't be added again.

Before the current path is resorted to, the path for the commands `\pathkeys`, `\pathkeysval`, `\ifpathkeysval`, etc. must be empty (i.e., no main and no subs). Therefore, in any given setting, the path that is dominant can be made current so that it isn't given in `\pathkeys`, `\pathkeysval`, `\ifpathkeysval`, etc. The non-dominant paths could then be listed in full. Of course, there can't be more than one current path.

1042                    Examples: `\pathkeys@currentpath`, etc.

```
\newcommand*\myframebox[1] []{%
\pathkeys@currentpath{KV/frame/framebox}%
\pathkeys{launch:#1}%
\begin{group}
\pathkeys@useshortcmds
\fboxsep\pkv{framesep}\fboxrule\pkv{framerule}\relax
\cptdimdef\boxwidth{\pkv{width}-2\fboxsep-2\fboxrule}%
\noindent\begin{lrbox}\@tempboxa
```

```

1050 \begin{minipage}[c][\height][s]\boxwidtha
1051 \killglue
1052 \begin{ttextalign}
1053 \textcolor{\pkv{textcolor}}{Arg-1: \pkv{arga}\endgraf Arg-2: \pkv{argb}}%
1054 \end{ttextalign}
1055 \end{minipage}%
1056 \end{lrbox}%
1057 \killglue
1058 \color{\pkv{framecolor}}%
1059 \ifpkv{putframe}\then\ovalbox{\fi
1060   \usebox\@tempboxa
1061 \ifpkv{putframe}\then\fi
1062 \endgroup
1063 }

1064 \begin{document}
1065 \myframebox[arga=Text-1,argb={Test text-2}\ ...\\test text-2},
1066   framerule=2pt,framecolor=blue,textcolor=purple,
1067   putframe=true, textalign=right]
1068 \end{document}

```

Examples: Tiling with pathkeys

```

1069 \documentclass{article}
1070 \usepackage{atbegshi,picture,graphicx,ifpdf}
1071 \usepackage{pathkeys}
1072 \makeatletter
1073 \pathkeys{wallpaper/fam}{\define*(cmd):
1074   viewport/00 00 100 100;
1075   xtilenr/2;
1076   ytilenr/2;
1077   wpxoffset/0pt;
1078   wpyoffset/0pt;
1079   inputpath//;
1080 }
1081 \newcommand*\mytilewallpaper[2][]{%
1082   \begingroup
1083     \pathkeys{currentpath/wallpaper/fam}%
1084     \pathkeys{set:#1}%
1085     \pathkeys{useshortcmds}
1086     \edef\ffileext{\ifpdf pdf\else eps\fi}%
1087     \edef\reserved@a{\pkv{inputpath}}%
1088     \edef\reserved@a{\expandafter\ltxkeys@stripallouterbraces
1089       \expandafter\reserved@a}%
1090     \edef\Ginput@path{\ifcsnullTF\reserved@a{}{\{\reserved@a\}}}%
1091     \cptdimdef{tilewidth}{(\paperwidth-\pkv{wpxoffset}*2)/\pkv{xtilenr}}%
1092     \cptdimdef{tileheight}{(\paperheight-\pkv{wpyoffset}*2)/\pkv{ytilenr}}%
1093     \cptdimdef{tileY}{-\paperheight+\pkv{wpyoffset}}%
1094     \tempcntb\z@
1095     \cptwhilenum{\tempcntb<\pkv{ytilenr}}{\do{%
1096       \edef\tileX{\pkv{wpxoffset}}%
1097       \tempcnta\z@
1098       \cptwhilenum{\tempcnta<\pkv{xtilenr}}{\do{%

```

```

1099     \leavevmode\@killglue
1100     \cptexpanded{\noexpand\put(\tileX,\tileY){\noexpand\includegraphics

1114   wpxoffset=2cm,wpyoffset=2cm,inputpath={./graphics}]{comet1}}
1115 \AtBeginShipout{%
1116   \AtBeginShipoutUpperLeft{%
1117     \ifnumoddTF\thepage{}{\expandafter\mytilewallpaper\wpspec}%
1118   }%
1119   x
1120 }\end{document}

```

### 16.3 Nested pathkeys

The command `\pathkeys` can be nested, as the following example shows:

Example: Nested pathkeys

```

1121 \def\mypath{fam/subfam/subsubfam}
1122 \pathkeys{\mypath/define:
1123   cmd/xwidth/\@tempdima/\def\y##1{#1yy##1};
1124   % The default, not callback, of ‘keya’ is \def\cmd{#1{#1}. The key
1125   % has no callback:
1126   cmd/keya/\def\cmd{#1{#1}};
1127   % The callback of ‘keyb’ says “if ‘keyb’ is ‘true’, define ‘keyc’”:
1128   bool/keyb/true/
1129   \pathkeys{\mypath/ifbool: keyb}{%
1130     \pathkeys{\mypath/define: cmd/keyc/xx/\def\cmd{####1{####1#1}}}{%
1131   }%
1132   % ‘keyd’ has no callback:
1133   \pathkeys{\mypath/define: choice/keyd.{yes,no}/yes}{%
1134   }%
1135   }%
1136 \pathkeys{\mypath/set: keyb=true}

```

Try to find out why the following produces an error:

Example: Nested pathkeys

```

1137 \def\mypath{fam/subfam/subsubfam}
1138 \pathkeys{\mypath/define:
1139   cmd/keya/keyadefault/

```

```

1140   \pathkeys{\mypath/define*: cmd/keyb/xx/\def\cmd{####1{####1}};
1141 }
1142 \pathkeys{\mypath/set: keya=bbb}

```

The reason is that `keyb` was defined when the default was being set up for `keya` after the definition of `keya`. The second setting of `keya` prompts an error that `keyb` is being redefined. Notice that `keyb` is to be defined uniquely by the flag `define*`. To avoid this type of error, you may consider removing `*` from `define*`.

## 16.4 Pathkeys as class or package options

To use the command `\pathkeys` for declaring class or package options, the user should simply call `\pathkeys` with the flag `declareoptions` (or `declareoptions*` for defining only unique options). The flags `executeoptions`, `processoptions` and `processoptions*` can be used to execute and process options, respectively. In this respect, although not necessary, you may want to change the default or current path to reflect the class file or package name.

### Example: Declaring and processing options

```

1143 \ProvidesPackage{mypackage}[2011/11/11 v0.1 My test package]
1144 \newpath{\mypath}{mypackage/myfunc/myfunckeys}
1145 % Declare three unique options:
1146 \pathkeys{\usepath{\mypath}/declareoptions*:
1147   cmd/opt1/12cm/\def\y##1{#1yy##1};
1148   bool/opt2/true/\ifpathkeysval{\usepath{\mypath}/opt2}\then
1149     \def\x{T}\else\def\x{F}\fi;
1150   ord/opt3/zz/\def\z##1{#1zz##1};
1151 }
1152 % Set up defaults for options 'opt1' and 'opt2', ignoring option 'opt3':
1153 \pathkeys{\usepath{\mypath}/executeoptions:
1154   opt1=10cm,opt2=true,opt3=yy [opt3]
1155 }
1156 % Ignore 'opt1' when processing options:
1157 \pathkeys{\usepath{\mypath}/processoptions*: [opt1]}

1158 \documentclass[opt1=2cm,opt2=false]{article}
1159 \usepackage[opt3=somevalue]{mypackage}

```

## 17 Some miscellaneous commands

Some of the macros used internally by the `ltxkeys` package are available to the user. A few of them are described below.

### 17.1 Trimming leading and trailing spaces

#### New macros: `\ltxkeys@trimspaces`, `\ltxkeys@trimspacesincs`

```

1160 \ltxkeys@trimspaces{(token)}{cs}
1161 \ltxkeys@trimspacesincs{cs}

```

The command `\ltxkeys@trimspaces` trims (i.e., removes) the leading and trailing spaces around `\token` and returns the result in the macro `\cs`. Forced (i.e., explicit) leading and trailing spaces around `\token` are removed unless they are enclosed in braces.

The command `\ltxkeys@trimspacesincs` trims the leading and trailing spaces around the token in the macro `\cs` and returns the result in `\cs`.

## 17.2 Checking user inputs

New macros: `\ltxkeys@checkchoice`, `\ltxkeys@checkinput`, `\CheckUserInput`

```
1162 \ltxkeys@checkchoice[⟨parser⟩]({⟨val⟩⟨order⟩}){⟨input⟩}{⟨nomin⟩}{⟨true⟩}
1163 \ltxkeys@checkchoice*[⟨parser⟩]({⟨val⟩⟨order⟩}){⟨input⟩}{⟨nomin⟩}{⟨true⟩}
1164 \ltxkeys@checkchoice+*[⟨parser⟩]({⟨val⟩⟨order⟩}){⟨input⟩}{⟨nomin⟩}{⟨true⟩}{⟨false⟩}
1165 \ltxkeys@checkchoice+*[⟨parser⟩]({⟨val⟩⟨order⟩}){⟨input⟩}{⟨nomin⟩}{⟨true⟩}{⟨false⟩}
1166 \ltxkeys@checkinput{⟨input⟩}{⟨nomin⟩}{⟨true⟩}{⟨false⟩}
1167 \CheckUserInput{⟨input⟩}{⟨nomin⟩}
```

The command `\ltxkeys@checkchoice` is a re-implementation of `xkeyval` package's command `\XKV@checkchoice` so as to accept arbitrary list parser `⟨parser⟩` and for more robustness. It checks the user input `⟨input⟩` against the list of nominations `⟨nomin⟩`. If the input is valid, the user input is returned in `⟨val⟩` and the numerical order (starting from zero) of the input in the nominations is returned in `⟨order⟩`<sup>‡5</sup>. If the input isn't valid, the user input is still returned in `⟨val⟩`, but `-1` is returned in `⟨order⟩`. `⟨parser⟩` is the list parser. The starred (`*`) variant of `\ltxkeys@checkchoice` will convert `⟨input⟩` into lowercase before checking it against the nominations. The plus (`+`) variant of `\ltxkeys@checkchoice` expects two branches (`⟨true⟩` and `⟨false⟩`) of callback at the end of the test. The non-plus variant expects only one branch (`⟨true⟩`) and will return error if the input is invalid<sup>‡6</sup>.

The commands `\ltxkeys@checkinput` and `\CheckUserInput` apply to comma-separated lists of nominations `⟨nomin⟩` and they always convert `⟨input⟩` to lowercase before checking it against the nominations `⟨nomin⟩`. The macro `\ltxkeys@checkinput` expects two branches of callback, while `\CheckUserInput` expects no callback. Instead, `\CheckUserInput` will toggle the internal boolean `\ifinputvalid` to `true` if the input is valid, and to `false` otherwise. The internal boolean `\ifinputvalid` could then be called by the user after the test.

## 17.3 Does a test string exist in a string?

New macros: `\ltxkeys@in`, `\ltxkeys@iffound`

```
1168 \ltxkeys@in{⟨teststr⟩}{⟨str⟩}
1169 \ltxkeys@in*{⟨teststr⟩}{⟨str⟩}{⟨true⟩}{⟨false⟩}
1170 \ltxkeys@iffound⟨teststr⟩\in⟨str⟩\then ⟨true⟩ \else ⟨false⟩ \fi
```

The unstarred variant of the command `\ltxkeys@in` is identical with L<sup>A</sup>T<sub>E</sub>X2<sub>ε</sub> kernel's (2011/06/27) `\in@`. The command `\in@` tests for the presence of `⟨teststr⟩` in `⟨str⟩` and returns the boolean `\ifin@` as `\iftrue` or `\iffalse`. The starred (`*`) variant of `\ltxkeys@in` returns two L<sup>A</sup>T<sub>E</sub>X branches `⟨true⟩` and `⟨false⟩`. On the other hand, the command `\ltxkeys@iffound` requires the first argument to be delimited by `\in` and the second argument by `\then`.

<sup>‡5</sup> The functions `⟨val⟩` and `⟨order⟩` are user-supplied macros.

<sup>‡6</sup> There is also `\ltxkeys@commacheckchoice`, whose parser is implicitly comma ‘,’ and does not need to be given by the user.

1171                    Example: `\ltxkeys@iffound`

```
\ltxkeys@iffound xx\in aax\then \def\x{T}\else \def\x{F}\fi
```

**Note 17.1** The command `\ltxkeys@iffound` trims leading and trailing spaces around the tokens `<teststr>` and `<str>` before the test! The commands `\ltxkeys@in` and `\ltxkeys@iffound` aren't expandable.

#### 17.4 Does a given pattern exist in the meaning of a macro?

1172                    New macro: `\ltxkeys@ifpattern`

```
\ltxkeys@ifpattern{\<teststr>}{\cmd}{\<true>}{\<false>}
```

The command `\ltxkeys@ifpattern` simply determines if the meaning of `\cmd` contains `<teststr>`. It returns `<true>` if `<teststr>` is found in the meaning of `\cmd`, and `<false>` otherwise.

#### 17.5 `\ifcase` for arbitrary strings

1173                    New macros: `\ltxkeys@ifcase`, `\ltxkeys@findmatch`

```
\ltxkeys@ifcase{\<teststr>}{{\<case-1>}:{\<cbk-1>},\dots,{\<case-n>}:{\<cbk-n>}}{\<true>}{\<false>}
```

1174                    `\ltxkeys@findmatch{\<teststr>}{{\<case-1>}:{\<cbk-1>},\dots,{\<case-n>}:{\<cbk-n>}}{\<fn>}`

The command `\ltxkeys@ifcase` tests `<teststr>` against `<case-i>`. If a match is found, the `<case-i>`'s callback `<cbk-i>` is returned in the macro `\currmatch` and `<true>` is executed. If at the end of the loop no match is found, `\ltxkeys@ifcase` returns empty `\currmatch` and executes `<false>`.

The command `\ltxkeys@findmatch` works like `\ltxkeys@ifcase` but executes the fallback `<fn>` (instead of `<true>` or `<false>`) when no match is found.

#### 17.6 Is the number of elements from a sublist found in a csv list $\geq n$ ?

1176                    New macro: `\ltxkeys@ifincsvlistTF`

```
\ltxkeys@ifincsvlistTF[Aparser]{\<nr>}{{\<sub>}}{\<main>}{{\<true>}}{\<false>}
```

1177                    `\ltxkeys@ifincsvlistTF★[Aparser]{\<nr>}{{\<sub>}}{\<main>}{{\<true>}}{\<false>}`

The command `\ltxkeys@ifincsvlistTF` checks if the number of elements of `<parser>`-separated (csv) list `<sub>` found in `<main>` is equal or greater than `<nr>`. The argument `<main>` is the main list and `<sub>` is the sublist of test strings. Normally, `<sub>` will be a user input and `<main>` the list of nominations. Neither `<main>` nor `<sub>` is expanded in the test. If the test is true, `\ltxkeys@itemspresent` returns all the elements found, `\ltxkeys@nitems` returns the number of elements found, and `<true>` is executed. If the test fails, `\ltxkeys@itemspresent` returns empty, `\ltxkeys@nitems` returns  $-1$ , and `<false>` is executed. The starred ( $\star$ ) variant of `\ltxkeys@ifincsvlistTF` will turn both input and nominations to lowercase before the test. The default values of the optional list `<parser>` and the optional number of elements to find `<nr>` are comma `,` and 1, respectively.

### 17.7 Is the number of elements from a sublist found in a tsv list $\geq n$ ?

New macro: `\ltxkeys@ifintsvlistTF`

```
1178 \ltxkeys@ifintsvlistTF{<nr>}{<sub>}{{<main>}}{<true>}{<false>}
1179 \ltxkeys@ifintsvlistTF*{<nr>}{<sub>}{{<main>}}{<true>}{<false>}
```

The command `\ltxkeys@ifintsvlistTF` checks if the number of elements of nonparser-separated (tsv) list `<sub>` found in `<main>` is equal or greater than `<nr>`. The argument `<main>` is the main list and `<sub>` is the sublist of test strings. Normally, `<sub>` will be a user input and `<main>` the list of nominations. Neither `<main>` nor `<sub>` is expanded in the test. If the test is true, `\ltxkeys@itemspresent` returns all the elements found, `\ltxkeys@nritems` returns the number of elements found, and `<true>` is executed. If the test fails, `\ltxkeys@itemspresent` returns empty, `\ltxkeys@nritems` returns  $-1$ , and `<false>` is executed. The starred ( $*$ ) variant of `\ltxkeys@ifintsvlistTF` will turn both input and nominations to lowercase before the test.

Normally, tsv-matching requires that the test strings in `<sub>` are unique in the nominations `<main>`. Some caution is, therefore, necessary when dealing with tsv lists.

### 17.8 Is the number of elements in a csv list $\geq n$ or $\leq n$ ?

New macro: `\ltxkeys@ifeltcountTF`

```
1180 \ltxkeys@ifeltcountTF[<parser>]{<rel>}{{<nr>}}{<list>}{<true>}{<false>}
1181 \ltxkeys@ifeltcountTF*{<parser>}{<rel>}{{<nr>}}{<listcmd>}{<true>}{<false>}
```

The command `\ltxkeys@ifeltcountTF` checks if the number of elements in `<parser>`-separated list `<list>` has relation `<rel>` ( $\geq <nr>$ ) with number `<nr>`. If the test is true, `<true>` is executed, otherwise `<false>` is executed. The starred ( $*$ ) variant of `\ltxkeys@ifeltcountTF` will expand `<listcmd>` once before the test. Double parsers and empty entries in `<list>` are ignored. The default values of the optional list `<parser>` and the optional relational type `<rel>` are comma `,`, and `=`, respectively. The number `<nr>` is a mandatory argument.

The following example returns `<false>` (i.e., `\meaning\x \rightarrow F`).

Example: `\ltxkeys@ifeltcountTF`

```
1182 \ltxkeys@ifeltcountTF[;]{<}>{2}{a;b;c}{\def\x{T}}{\def\x{F}}
```

### 17.9 What is the numerical order of an element in a csv list?

New macro: `\ltxkeys@getorder`

```
1183 \ltxkeys@getorder[<parser>]{<elt>}{<list>}
1184 \ltxkeys@getorder*{<parser>}{<elt>}{<listcmd>}
```

The command `\ltxkeys@getorder` returns in `\ltxkeys@order` the numerical order of `<elt>` in `<parser>`-separated `<list>` or `<listcmd>`. The value of `\ltxkeys@order` is the numerical order of the first match found. The count starts from zero (0). The starred ( $*$ ) variant will expand `<listcmd>` once before commencing the search for `<elt>`. If no match is found, `\ltxkeys@order` returns  $-1$ , which can be used for taking further decisions.

## 17.10 List normalization

New macros: `\ltxkeys@commanormalize`, `\ltxkeys@kvnormalize`

```
1185 \ltxkeys@commanormalize{\list}{\cmd}
1186 \ltxkeys@commanormalizeset{{\list-1}}{\cmd-1}, ..., {\list-n}{\cmd-n}}
1187 \ltxkeys@kvnormalize{\list}{\cmd}
1188 \ltxkeys@kvnormalize{\list}{\cmd}
```

These commands will normalize the comma-separated `\list` (or `\list-i`) and return the result in `\cmd` (or `\cmd-i`). For the command `\ltxkeys@kvnormalize`, `\list` is assumed to be a list of `\key=\value` pairs. Normalization implies changing the category codes of all the active commas to their standard values, as well as trimming leading and trailing spaces around the elements of the list and removing consecutive multiple commas. Thus empty entries that are not enforced by curly braces are removed. Besides dealing with multiple commas and the spaces between entries, the command `\ltxkeys@kvnormalize` removes spaces between keys and the equality sign, and multiple equality signs are made only one. Further, the category codes of comma and the equality sign are made normal throughout the list.

## 17.11 Parsing arbitrary csv or kv list

New macro: `\ltxkeys@parse`

```
1189 \ltxkeys@parse<flag>[<parser>]{\list}
1190 \ltxkeys@parse*{<flag>[<parser>]{\listcmd}}
```

The unexpandable command `\ltxkeys@parse` is the list processor for the `ltxkeys` package. It can process both arbitrary `<parser>`-separated lists and `\key=\value` pairs. The `<flag>`, which must lie in the range (0, 3), determines the type of processing that is required. The admissible values of `<flag>` and their meaning are given in Table 4. The macro `\ltxkeys@parse` loops over the given `<parser>`-separated `\list` and execute the user-defined, one-parameter command `\ltxkeys@do` for every item in the list, passing the item as an argument and preserving outer braces. The default value of `<parser>` is comma ‘,’. The starred (\*) variant of `\ltxkeys@parse` will expand `\listcmd` once before commencing the loop.

Table 4: Flags for command `\ltxkeys@parse`

Flag	Meaning
0	<code>\list</code> is assumed to be an ordinary list (i.e., not a list of <code>\key=\value</code> pairs); it isn’t normalized by <code>\ltxkeys@parse</code> prior to parsing.
1	<code>\list</code> is assumed to be an ordinary list (i.e., not a list of <code>\key=\value</code> pairs); it is normalized by <code>\ltxkeys@parse</code> prior to parsing.
2	<code>\list</code> is assumed to be a list of <code>\key=\value</code> pairs; it isn’t normalized by <code>\ltxkeys@parse</code> prior to parsing.
3	<code>\list</code> is assumed to be a list of <code>\key=\value</code> pairs; it is normalized by <code>\ltxkeys@parse</code> prior to parsing.

Here are some points to note about the list processor `\ltxkeys@parse`:

- a) If an item contains `<parser>`, it must be wrapped in curly braces when using `\ltxkeys@parse`, otherwise the elements may be mixed up during parsing. The braces will persist thereafter, but will of course be removed during printing (if the items are printed).

- b) White spaces before and after the list separator are always ignored by the normalizer called by `\ltxkeys@parse`. If an item contains `<parser>` or starts with a space, it must, therefore, be wrapped in curly braces before calling `\ltxkeys@parse`.
- c) Since when `<flag>` is 0 or 2 the command `\ltxkeys@parse` doesn't call the normalizer, in this case it does preserve outer/surrounding spaces in the entries. Empty entries in `<list>` or `<listcmd>` will be processed by `\ltxkeys@parse` if the boolean `\ifltxkeys@useempty` is true. You may thus issue the command `\ltxkeys@useemptytrue` before calling `\ltxkeys@parse`. The ability to parse empty entries is required by packages that use empty key prefixes, and/or families<sup>†7</sup>. `\ifltxkeys@useempty` is false by default.
- d) The command `\ltxkeys@parse` can be nested to any level and can be mixed with other looping macros.
- e) In the command `\ltxkeys@parse`, it is always possible to break out of the loop prematurely at any level of nesting, simply by issuing the command `\loopbreak`. Breaking an inner loop doesn't affect the continuation of the outer loop, and vice versa.
- f) The argument of the one-parameter command `\ltxkeys@do` can be passed to a multi-parameter command, or to a command that expects delimited arguments.

## 17.12 Expandable list parser

New macro: `\ltxkeys@declarelistparser`

```
1191 \ltxkeys@declarelistparser<iterator>{<parser>}
1192 \def<processor>#1{...#1...}
1193 <iterator>{<list>}<processor>
1194 <iterator>!{<list>}<processor>
```

Given a parser (or list separator) `<parser>`, the command `\ltxkeys@declarelistparser` can be used to define an expandable list iterator `<iterator>`. The item processor `<processor>` should be a one-parameter macro, which will receive and process each element of `<list>`. The optional exclamation mark (`!`) determines whether or not the processor is actually expanded and executed in the current expansion context. If `!` is given, the processor is expanded and executed, otherwise it is merely given the elements as argument without expansion. In general, `<list>` isn't normalized, but is expanded once, before commencing the loop. The list can be normalized by the command `\csv@normalize` of the `catoptions` package before looping<sup>†8</sup>. The following example demonstrates the concept. The user can insert `\listbreak` as an item in the list to break out of the iteration prematurely.

Examples: `\ltxkeys@declarelistparser`

```
1195 \ltxkeys@declarelistparser\iterator{;}
1196 \def\do#1{#1}
1197 % The following example will yield '\x=macro:->\do{a}\do{b}\do{c}':
1198 \edef\x{\iterator{a;b;c}\do}
1199 % The following example will yield 'abc':
1200 \edef\x{\iterator!{a;b;c}\do}

1201 % The following example will add 'a,b,c' to macro \y:
1202 \ltxkeys@declarelistparser\doloop{,}
1203 \doloop{a,b,c}{\cptaddtolist\y}
```

<sup>†7</sup> The use of empty key prefixes, families and paths is, in general, not advisable.

<sup>†8</sup> The `catoptions` package is loaded by the `ltxkeys` package. The `ltxtools-base` package provides the command `\ltsdeclarelistparser`, which works similar to the macro `\ltxkeys@declarelistparser` but has a dynamic, expandable list normalizer for arbitrary list parsers/separators.

```

1204 % The following example will add 'd,e' to macro \y and ignore 'f':
1205 \doloop!{d,e,\listbreak,f}{\cptaddtolist\y}

1206 % Nesting of the <iterator> is possible:
1207 \ltxkeys@declarelistparser\alistparser{},}
1208 \ltxkeys@declarelistparser\blistparser{;}
1209 \def\@do#1{#1}
1210 \def\do#1{#=#1=\blistparser!{x;y;z}\@do}
1211 \edef\x{\alistparser!{a,b,c}\do}
1212 % This gives: \x=macro:->=a=xyz=b=xyz=c=xyz

```

### 17.13 Remove one or all occurrences of elements from a csv list

New macro: `\ltxkeys@removeelements`

```

1213 \ltxkeys@removeelements[<parser>](<nr>){<listcmd>}{<sublist>}{}{<fd>}{<nf>}
1214 \ltxkeys@removeelements★[<parser>](<nr>){<listcmd>}{<sublist>}{}{<fd>}{<nf>}

```

The command `\ltxkeys@removeelements` removes `<nr>` number of each element of `<sublist>` from `<listcmd>`. The default values of the optional list `<parser>` and the optional maximum number of elements to remove `<nr>` are comma `,` and `1`, respectively. If at least one member of `<sublist>` is found and removed from `<listcmd>`, then the callback `<fd>` is returned and executed, otherwise `<nf>` is returned. Both `<fd>` and `<nf>` provide some fallback following the execution of `\ltxkeys@removeelements`. The challenge to the user is to remember that the command `\ltxkeys@removeelements` requires these callbacks, which may both be empty. The starred (`*`) variant of `\ltxkeys@removeelements` will remove from `<listcmd>` all the members of `<sublist>` found irrespective of the value of `<nr>`. The optional `<nr>` is therefore redundant when the starred (`*`) variant of `\ltxkeys@removeelements` is called. Here, `<sublist>` is simply `<parser>`-separated.

Example: `\ltxkeys@removeelements`

```

1215 \def\xx{a;b;c;d;d;e;f;c;d}
1216 % Remove at most 2 occurrences of 'c' and 'd' from \xx:
1217 \ltxkeys@removeelements[;](2)\xx{c;d}{\def\x{done}}{\def\x{nil found}}
1218 % Remove all occurrences of 'c' and 'd' from \xx:
1219 \ltxkeys@removeelements★[;]\xx{c;d}{\def\x{done}}{\def\x{nil found}}

```

### 17.14 Replace one or all occurrences of elements in a csv list

New macro: `\ltxkeys@replaceelements`

```

1220 \ltxkeys@replaceelements[<parser>](<nr>){<listcmd>}{<sublist>}{}{<fd>}{<nf>}
1221 \ltxkeys@replaceelements★[<parser>](<nr>){<listcmd>}{<sublist>}{}{<fd>}{<nf>}

```

The command `\ltxkeys@replaceelements` replaces `<nr>` number of each element of `<sublist>` in `<listcmd>`. The default values of the optional list `<parser>` and the optional maximum number of elements to replace `<nr>` are comma `,` and `1`, respectively. If at least one member of `<sublist>` is found and replaced in `<listcmd>`, then the callback `<fd>` is returned and executed, otherwise `<nf>` is returned. Both `<fd>` and `<nf>` provide some fallback following the execution of `\ltxkeys@replaceelements`. The challenge to the user is to remember that the command `\ltxkeys@replaceelements` requires these callbacks, which may both be empty. The starred (`*`)

variant of `\ltxkeys@replaceelements` will replace in `<listcmd>` all the members of `<sublist>` found irrespective of the value of `<nr>`. The optional `<nr>` is therefore redundant when the starred (\*) variant of `\ltxkeys@replaceelements` is used. Here, the syntax of `<sublist>` is as follows:

Sublist for `\ltxkeys@replaceelements`

```
1222 {{<old-1>}<new-1>}{<parser>}...{<parser>}{{<old-n>}<new-n>}}
```

where `<old-i>` is the element to be replaced and `<new-i>` is its replacement.

Example: `\ltxkeys@replaceelements`

```
1223 \def\xx{a;b;c;d;d;e;f;c;d}
1224 % Replace at most 2 occurrences of 'c' and 'd' in \xx with 's' and 't',
1225 % respectively:
1226 \ltxkeys@replaceelements[;](2)\xx{c{s};d{t}}{\def\x{done}}{\def\x{nil found}}
1227 % Replace all occurrences of 'c' and 'd' in \xx with 's' and 't':
1228 \ltxkeys@replaceelements*[;]\xx{c{s};d{t}}{\def\x{done}}{\def\x{nil found}}
```

## 17.15 Stripping outer braces

The list and key parsers of the `ltxkeys` package preserve outer braces, but sometimes it is needed to rid a token of one or more of its outer braces. This can be achieved by the following commands:

New macros: `\ltxkeys@stripNouterbraces`, `\ltxkeys@stripallouterbraces`, etc.

```
1229 \ltxkeys@stripNouterbraces<nr>{<token>}
1230 \ltxkeys@stripallouterbraces{<token>}
1231 \ltxkeys@stripallouterbracesincs{<cmd>}
```

The command `\ltxkeys@stripNouterbraces` strips `<nr>` number of outer braces from `<token>`. The command `\ltxkeys@stripallouterbraces` strips all outer braces from `<token>`. The command `\ltxkeys@stripallouterbracesincs` strips all the outer braces in the top content of the command `<cmd>`. All these commands are expandable. Normally, `<token>` wouldn't be expanded by these commands in the process of stripping off outer braces.

Examples: `\ltxkeys@stripNouterbraces`, `\ltxkeys@stripallouterbraces`, etc.

```
1232 \toks@\expandafter\expandafter\expandafter
1233   {\ltxkeys@stripNouterbraces{2}{{{\y}}}}
1234 \edef\x{\unexpanded\expandafter\expandafter\expandafter
1235   {\ltxkeys@stripNouterbraces@m{{{\y}}}}}
1236 \edef\x{\ltxkeys@stripallouterbraces{{{\y}}}}
```

## 18 To-do list

This section details additional package features that may become available in the foreseeable future. User views are being solicited in regard of the following proposals.

### 18.1 Patching key macros

Patching the macro of an existing key, instead of redefining the key. `etoolbox` package's `\patchcmd` doesn't permit the patching of commands with nested parameters. But since key macros may have nested parameters, a new patching scheme is to be first explored.

## 18.2 Modifying the dependant keys of an existing style key

New macros: `\ltxkeys@adddepkeys, etc`

```
1237 \ltxkeys@adddepkeys[<pref>]{<fam>}{{<paren>}{<deps>}}
1238 \ltxkeys@removedepkeys[pref]{fam}{<paren>}{<deps>}
1239 \ltxkeys@replacedepkeys[pref]{fam}{<paren>}{<olddeps>}{<newdeps>}
```

Here, `<paren>` is the parent key of dependants keys; `<deps>` is the full specification of new or existing dependant keys (as in [subsection 3.4](#)), with their default values and callbacks; `<olddeps>` are the old dependants to replace with `<newdeps>`. This would require patching macros of the form `\<pref>@<fam>@<key>@dependants`, which might have nested parameterized-commands.

## 18.3 Toggle and switch keys

Introduce toggle keys and switch keys, but in practice who needs them? I would really need user views before implementing this feature. Toggles and switches, found in, e.g., the `catoptions` package, are more efficient than conventional booleans in the sense that each of them introduces and requires only one command, while each native boolean defines and requires up to three commands. However, toggles and switches haven't yet made it into the popular imagination of T<sub>E</sub>X users.

## 19 Version history

The following change history highlights significant changes that affect user utilities and interfaces; changes of technical nature are not documented in this section. The star sign (\*) on the right-hand side of the following lists means the subject features in the package but is not reflected anywhere in this user guide.

### Version 0.0.3 [2011/12/17]

More flags (`preset`, `postset`, `setrm`, etc.) have been introduced for pathkeys . . . . . [section 16](#)

### Version 0.0.2 [2011/09/01]

Pathkeys introduced . . . . . [section 16](#)

User guide completed. . . . . \*

### Version 0.0.1 [2011/07/30]

First public release. . . . . \*
