1 Introduction

These packages offer a series of extensions to the standard ${\rm IAT}_{\rm E}{\rm X}$ tabular environment. Their respective functions are:

^{*}catalogued "active author"

 $^{^\}dagger \textsc{Documentation}$ originally put together by Robin Fairbairns

- **multirow** which provides a construction for table cells that span more than one row of the table;
- **bigstrut** which creates struts which (slightly) stretch the table row in which they sit.
- **bigdelim** which creates an appropriately-sized delimiter (for example, brace, parenthesis or bracket) to fit in a single multirow, to indicate a relation-ship between other rows; and

2 Changes in version 2.0

- \multirow now has an first optional parameter $[\langle vpos \rangle]$.
- The $\langle width \rangle$ parameter can be specified as = to use the defined width of the column in which the \multirow appears.
- Optional prefix letters (t, b) for the *(bigstruts)* parameter (see section 3.4).
- Package option debug.
- Package option longtable to work around a bug in longtable. See section 3.5.
- Package option supertabular to better support supertabular. See section 3.6.
- Better positioning in some cases.
- Lots of documentation.
- The distribution is now based on a .dtx file.
- Backwards compatible with v1.6.

3 Using multirow

\multirow \multirow sets a piece of text in a tabular or similar environment, spanning multiple rows. We will call the block of rows and columns that the text spans the multirow block. Usually this covers one column, but by combining it with \multicolumn more columns can be covered.

The basic syntax is:

```
\operatorname{vultirow}[\langle vpos \rangle] \{\langle nrows \rangle\} [\langle bigstruts \rangle] \{\langle width \rangle\} [\langle vmove \rangle] \{\langle text \rangle\}
```

where

- (vpos) defines the vertical positioning of the text in the multirow block. The default is [c] which means the text will be vertically centered. Other options are [t] for top alignment and [b] for bottom alignment.
- $\langle nrows \rangle$ is the number of rows to span. You should leave the other rows empty at this column, otherwise the stuff created by \multirow will over-write it. With a positive value of $\langle nrows \rangle$ the spanned columns are this row and $(\langle nrows \rangle -1)$ rows below it. With a negative value of $\langle nrows \rangle$ they are this row and $(1-\langle nrows \rangle)$ above it.

 $\langle bigstruts \rangle$ is mainly used if you've used the bigstrut package. In that case it is the total number of uses of \bigstrut within the rows being spanned. Count 2 uses for each \bigstrut, 1 for each \bigstrut[$\langle x \rangle$] where $\langle x \rangle$ is either t or b. The default is 0.

The $\langle bigstruts \rangle$ parameter can optionally be preceded by a prefix letter t, b or tb for finer control. See section 3.4 for details. The letter may be separated from the number by a space character.

- (width) is the width to which the text is to be set. Special values are * to indicate that the text parameter's natural width is to be used, and = to indicate that the specified width of the column in which the \multirow entry is set should be used.
- $\langle vmove \rangle$ is a length used for fine tuning: the text will be raised (or lowered, if $\langle vmove \rangle$ is negative) by that length above (below) wherever it would otherwise have gone.
- $\langle text \rangle$ is the actual text of the construct. If the width was set explicitly, the text will be set in a **\parbox** of that width; you can use **** to force linebreaks where you like.

If the width was given as * the text will be set in LR mode. If you want a multiline entry in this case you could use a tabular or array environment in the text parameter. See for example the minitab below.

The width can also be given as = when the \multirow entry is given in a column that has a defined width, for example in a p{} column, an X column in tabularx or a L, C, R or J column in a tabulary environment. The text will be set in a \parbox of that width. If you give "=" in other situations, you will get strange results (usually a too wide column).

N.B. \multirow can be used in the tabular environment and most derivatives of it, for example tabularx, tabulary, supertabular, xtab, longtable, tabu, booktabs and ctable. For some of these you have to pay special attention to certain cases, see below.

Just before $\langle text \rangle$ is expanded, the \multirowsetup macro is expanded to set up any special environment. Initially, \multirowsetup contains just \raggedright. It may be redefined with \renewcommand.

If you want to use both \multirow and \multicolumn on the same entry, you must put the \multirow inside the \multicolumn. The other way around will not work. For example:

\multicolumn{2}{c}{\multirow{3}{*}{Multi-multi}}

3.1 Package Options

The following options are defined:

\multirowsetup

multirowdebugtrue multirowdebugfalse When such a command is placed just before a \multirow, it applies only to that specific \multirow entry.

longtable The longtable option redefines the \cline macro to work around a bug in the longtable package. See section 3.5.

3.2 Examples

An example with both multirow and bigstrut):

```
\newcommand{\minitab}[2][1]{\begin{tabular}#1}#2\end{tabular}}
\begin{tabular}{|c|c|}
\hline
\t \ g2a \ g2a \
     & Column g2b \\
     & Column g2c \backslash\backslash
     & Column g2d \setminus
\hline
\multirow{3}[6]*{Common g text} & Column g2a\bigstrut\\\cline{2-2}
     & Column g2b \bigstrut\\\cline{2-2}
     & Column g2c \bigstrut\\
\hline
\multirow{4}[8]{1in}{Common g text, but a bit longer.} &
                                   Column g2a\bigstrut\\\cline{2-2}
     & Column g2b \bigstrut\\\cline{2-2}
     & Column g2c \bigstrut\\\cline{2-2}
     & Column g2d \bigstrut\\
\hline
\t(4)*{\mintab[c]{Common \ g text}} \& Column g2a\)
     & Column g2b \\
     & Column g2c \setminus
     & Column g2d \\
\hline
\end{tabular}
```

which will appear as:

Common a tout	Column g2a	
	Column g2b	Normal case
Common g text	Column g2c	Normai case
	Column g2d	
	Column g2a	
Common g text	Column g2b	With \bigstruts and $*$ as $\langle width \rangle$
	Column g2c	
	Column g2a	
Common g text, but a bit longer.	Column g2b	With \bigstruts and normal $\langle width$
	Column g2c	
	Column g2d	
	Column g2a	
Common	Column g2b	Multiline text in \multirow
g text	Column g2c	
	Column g2d	

An example with the "=" $\langle width \rangle$ specifier in a tabulary (Note: The braces around the = may be omitted):

```
\setlength{\extrarowheight}{2pt}
\hline
 All human beings are born free and equal in dignity and rights. &
    \multirow{2}{=}{Everyone is entitled to all the rights and
    freedoms set forth in this Declaration, without distinction of
    any kind, such as race, colour, sex, language, religion,
    political or other opinion, national or social origin, property,
    birth or other status.}
 & Everyone has the right to life, liberty and security of person. 
 \
cline{1-1}\cline{3-3}
    No one shall be held in slavery or servitude; slavery and the
    slave trade shall be prohibited in all their forms. &
 & No one shall be subjected to torture or to cruel, inhuman or
 degrading treatment or punishment. 
 \
\hline
\end{tabulary}
```

All human beings are born free and equal in dignity and rights.	Everyone is entitled to all the rights and freedoms set forth in this Declaration, without distinction of any kind, such as race, colour,	Everyone has the right to life, liberty and security of person.
No one shall be held in slavery or servitude; slavery and the slave trade shall be prohibited in all their forms.	sex, language, religion, political or other opinion, national or social origin, property, birth or other status.	No one shall be subjected to torture or to cruel, inhuman or degrading treatment or punishment.

- A few observations about this example:
- 1. The middle column is the \multirow. You would expect it to be vertically centered, but it isn't. This is because \multirow doesn't know the height of the box. The only estimate \multirow can make about the height is the number of rows × the normal height of a row. It tries to center the text in that space, but that space is too low in this example. Therefore the text is at the top of the box. If you want it to be centered, you have to supply a $\langle vmove \rangle$ parameter to shift it down.
- 2. We have used an $\ensuremath{\backslash}extrarowheight^1$ of 2pt, to make a bit room between the \hline and the following text. However, this is not applied to the \multirow , because this is thought to be centered. In this case you can give the $\langle vpos \rangle$ parameter as [t], in which case \multirow will do the proper positioning.

Now with a negative $\langle nrows \rangle$.

```
\setlength{\extrarowheight}{2pt}
\begin{tabulary}{11cm}{|L|L|}
 \hline
 All human beings are born free and equal in dignity and rights. &
 & Everyone has the right to life, liberty and security of person. 
 \
cline{1-1}\cline{3-3}
    No one shall be held in slavery or servitude; slavery and the
     slave trade shall be prohibited in all their forms. &
     \multirow{-2}{=}[12mm]{Everyone is entitled to all the rights and
    freedoms set forth in this Declaration, without distinction of
    any kind, such as race, colour, sex, language, religion,
    political or other opinion, national or social origin, property,
    birth or other status.}
 & No one shall be subjected to torture or to cruel, inhuman or
 degrading treatment or punishment. \\
\hline
\end{tabulary}
```

All human beings		Everyone has
are born free and	Everyone is entitled to all	the right to life,
equal in dignity	the rights and freedoms set	liberty and
and rights.	forth in this Declaration,	security of
	without distinction of any	person.
No one shall be	kind, such as race, colour,	No one shall be
held in slavery or	sex, language, religion,	subjected to
servitude; slavery	political or other opinion,	torture or to
and the slave	national or social origin,	cruel, inhuman
trade shall be	property, birth or other	or degrading
prohibited in all	status.	treatment or
their forms.		punishment.

In this case the text would be centered somewhere in the bottom row, which would make it stick out of the bottom. Therefore we applied a $\langle vmove \rangle$ of 12mm. The $\langle vmove \rangle$ usually requires some experimentation.

 $^{^{1}}$ This is only available with the array package, which tabulary includes automatically.

3.3 Fine Tuning

If any of the spanned rows are unusually large, or if you're using the bigstrut package and \bigstruts are used asymetrically about the centerline of the spanned rows, the vertical centering may not come out right. Use the $\langle vmove \rangle$ parameter in this case.

It's just about impossible to deal correctly with descenders. The text will be set up centred, but it may then have a baseline that doesn't match the baseline of the stuff beside it, in particular if the stuff beside it has descenders and $\langle text \rangle$ does not. This may result in a small misalignment. About all that can be done is to do a final touchup on $\langle text \rangle$, using the $\langle vmove \rangle$ optional parameter. (Hint: If you use a measure like .1ex, there's a reasonable chance that the $\langle vmove \rangle$ will still be correct if you change the point size.)

\multirow is mainly designed for use with tabular, as opposed to array, environments. It might not work well in an array environment if there are big formulas in some rows; in that case you can use the $\langle vmove \rangle$ parameter to refine the result.

In some cases you might want to align the multirow entry with the top of the other row cells, for example if you have a large capital in it. when you use $\langle vpos \rangle = [t]$, the baselines will be aligned, which is the wrong thing in this case. You can then do the positioning with the $\langle vmove \rangle$ parameter and let LATEX calculate the amount. For example:

```
\usepackage{calc}
\newlength{\shiftdown}
\setlength{\shiftdown}{\heightof{\Huge\bfseries B}-\heightof{f}}
. . .
\begin{tabular}{cll}
  \toprule
  \multirow[t]{5}{*}[-\shiftdown]{\Huge\bfseries B}
                     & foo & Lorem ipsum dolor sit
                                                          //
                     & bar & Maecenas sed purus
                                                          //
                     & baz & Nullam luctus id tellus
                                                         \backslash \backslash
                     & qux & Aenean consequat commodo \\
 \bottomrule
\end{tabular}
       foo
             Lorem ipsum dolor sit
В
       bar
             Maecenas sed purus
             Nullam luctus id tellus
       baz
```

If you use \multirow with the colortbl package you have to take precautions if you want to colour the column that has the \multirow in it. The colortbl package works by colouring each cell separately. So if you use \multirow with a positive $\langle nrows \rangle$ value, colortbl will first color the top cell, then \multirow will typeset $\langle nrows \rangle$ cells starting with this cell, and later colortbl will color the other cells, effectively hiding the text in that area. This can be solved by putting the \multirow in the last row with a negative $\langle nrows \rangle$ value. See, for example:

Aenean consequat commodo

qux

\begin{tabular}{l>{\columncolor{yellow}}}}

```
aaaa & \\
cccc & \\
dddd & \multirow{-3}*{bbbb}\\
\end{tabular}
```

which will produce:

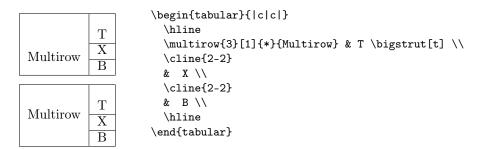

aaaa	
cccc	bbbb
dddd	

3.4 Fine tuning the $\langle bigstruts \rangle$ parameter

 $\mbox{multirow}$ can calculate the height of the required multirow box from $\langle nrows \rangle$ and $\langle bigstruts \rangle$, supposed that all the rows don't have "unusual heights. However, there are cases when this is not enough to properly position the box, especially when there is a $\mbox{bigstrut}$ on top of the first row and/or one on the bottom of the last row. In that case $\mbox{multirow}$ should be given additional information. This is done by prefixing the $\langle bigstruts \rangle$ parameter with a letter (or two) indicating which of these two are present.

See the following examples:

(in these examples we have $\stlength{\bigstrutjot}{10pt}$ to make the effect clearly visible)

In the top box in the above example the text "Multirow" should be centered, but it is a bit below the center, because of the $\bigstrut[t]$ in the top row. We can correct this by giving the $\langle bigstruts \rangle$ parameter as "t 1", indicating a bigstrut in the top. This is done in the bottom box, where $\multirow{3}[t 1]{*}{Multirow}$ is used.

A second example:

Multirow X B	<pre>\begin{tabular}{ c c } \hline & T \\ \cline{2-2} & X \\</pre>
Multirow T X B	<pre>\cline{2-2} \multirow[t]{-3}[1]{*}{Multirow} & B \bigstrut[b] \\ \hline \end{tabular}</pre>

In the top box the $\multirow[t]$ should be positioned on the same height as the T, but it is too high, because there is a \bigstrut in the bottom. We can correct that by specifying the $\langle bigstruts \rangle$ parameter as "b 1", i.e. using $\multirow[t]{-3}[b 1]{*}{Multirow}$.

The possibilities for the prefix are:

- t There is a bigstrut in the top, i.e. a \bigstrut or \bigstrut[t] in the top row.
- b There is a bigstrut in the bottom, i.e. a \bigstrut or \bigstrut[b] in the bottom row.
- tb They are both present. Note: this cannot be given as bt.

The space between the letter(s) and the number is optional. Please note that the prefix does not depend on whether the \multirow is in the top or the bottom row.

3.5 Use with longtable

It is possible to use \multirow in a longtable environment (as well as in its descendent longtabu). However, care must be taken that the longtable doesn't break the multirow entry when it is near the bottom of the page. For example:

Sept. 21	09:00	event 1
Sept. 22	10:00	event 2
	10:00	event 3
Sept. 23	12:00	event 4
	15:00	event 5
Sept. 24	09:00	event 6

In this case if the "Sept. 23" entry comes close to the bottom of the page, you want to prevent the pagebreak to occur in the middle of this entry. You can do this by ending the intermediate rows with $\$ instead of $\$.

There is, however, a bug in longtable, that causes the * not to work if it is followed by a \cline, like in the following example:

```
\multirow{3}*{Sept. 23} & 10:00 & event 3 \\*
\cline{2-3}
```

& 12:00 & event 4 * \cline{2-3} & 15:00 & event 5 \\

multirow has a package option longtable that redefines \cline so that the * will also work when followed by \cline. The code comes from David Carlisle.

3.6 Use with supertabular

With the package supertabular (or the augmented version xtab) there is the same requirement to keep the rows of a multirow together when a pagebreak occurs. Unfortunately, supertabular does not have a way to specify that a pagebreak should be suppressed. I.e. * does not suppress a pagebreak. Therefore multirow provides a package option supertabular that redefines * inside a supertabular to suppress the pagebreak. You should use this to end the intermediate rows in a multirow block. However, this does not cause supertabular to consider breaking the page before the \multirow, contrary to longtable. Thus the table may become too long.

\STneed

Therefore when the supertabular option is given, multirow also provides a command \STneed to be used in a supertabular that specifies how much space we need on the page. Then if there is not enough space, a pagebreak will occur at that place. For example:

```
\tabletail{\hline}
\begin{supertabular}{|1|1|1|}
\ldots & \ldots & \ldots \\
\hline
Sept. 20 & 10:00 & event 1\\
\hline
Sept. 21 & 10:00 & event 2\\
\hline
Sept. 22 & 10:00 & event 3\\
\hline
STneed {2cm}
\multirow{3}*{Sept. 23} & 10:00 & event 4\\*
cline{2-3}
                        & 12:00 & event 5 \\*
cline{2-3}
                        & 15:00 & event 6 \\
\hline
Sept. 24 & 09:00 & event 7 \\
\hline
\ldots & \ldots & \ldots \\
```

You will have to experiment a bit with the value to see what works. Sometimes it is better to exaggerate the required space a bit.

3.7 Dealing with tall entries

Sometimes there are rows that are taller than what is expected. This section gives some hints how to deal with these situations. There are two cases:

1. When there is an exceptionally tall row outside of the multirow block the positioning of the \multirow might be wrong. This is because \multirow does not have information about the heights of the rows. This can happen for example when a large formula is entered in a cell, or a multi-line paragraph in a [{}] column. An example:

	Monday	Rain most of the day
Week 38	Tuesday	Sunny with some clouds
	Wednesday	A clear day with a lot
		of sunshine. However,
		the strong wind will bring
		down the temperature.

The \multirow is positioned on the second row, because it specifies that it should cover 3 rows. However, the second row is not the vertical center in this case because the third row is much taller.

To remedy this, the $\langle vmove \rangle$ parameter could be used. However, in this case it would be easier to pretend that \multirow spans 6 rows (the total number of lines in the last column). So use \multirow{6}... and we get:

	Monday	Rain most of the day
	Tuesday	Sunny with some clouds
Week 38	Wednesday	A clear day with a lot
Week Jo		of sunshine. However,
		the strong wind will bring
		down the temperature.

2. The second case is when the \multirow entry is taller than the surrounding normal rows. In that case the multirow text will stick out of its block. We must now enlarge the other rows, and that is something \multirow cannot do.

An example: (Don't take this as a medical advice. The names are fake anyway.)

```
\mathbb{2}{|1|}{Spirino}
                     & \multirow{3}={Confusion,
                       hallucinations, rapid breathing,
                       seizure (convulsions);
                       upset stomach, heartburn; severe nausea,
                       vomiting, or stomach pain or mild headache.} \\
cline{1-2}
 & initial: 200 mg/day & \\
cline{1-2}
  & maintenance: 100-400 mg/day & \\
\hline
\mathbb{2}{|1|}{Conzac}
                     & \multirow{3}={Anxiety; nervousness;
                      insomnia; anorexia; mild bradycardia;
                      SA node slowing; weight loss;
                      solar photosensitivity; hyponatremia;
                      sexual dysfunction (both genders); may
                      alter glycemic control in diabetic patients.} \\
cline{1-2}
 & initial: 10 mg/day & \backslash\backslash
cline{1-2}
  & maintenance: 10-40 mg/day & \\
\hline
\end{tabular}
```

Medicine & dose	Possible Side effects
Spirino	Confusion, hallucinations, rapid
initial: 200 mg/day	breathing, seizure (convulsions);
maintenance: 100-400 mg/day	upset stomach, heartburn;
Conzac	Severety, a use a o use with the severe ty a use a o use of the severe ty a usevere ty a use of the severe ty a use of the severe ty a us
initial: 10 mg/day	atromexcia;paiiildobradlyc hedida.ch4.
maintenance: 10-40 mg/day	node slowing; weight loss; solar
	photosensitivity; hyponatremia;
	sexual dysfunction (both
	genders); may alter glycemic
	control in diabetic patients.

Both \multirow entries are too high; the first sticks out into the second entry, and the second one sticks out of the table.

There are two ways we can correct this: The simplest would be to add extra empty rows to cover the overlapping space. For the first entry that would be 2 extra rows; for the second 4. So we add twice & & \\ before the third \hline, and four of these before the last \hline. This gives us just the correct table:

Medicine & dose	Possible Side effects
Spirino	Confusion, hallucinations, rapid
initial: 200 mg/day	breathing, seizure (convulsions);
maintenance: 100-400 mg/day	upset stomach, heartburn;
	severe nausea, vomiting, or
	stomach pain or mild headache.
Conzac	Anxiety; nervousness; insomnia;
initial: 10 mg/day	anorexia; mild bradycardia; SA
maintenance: $10-40 \text{ mg/day}$	node slowing; weight loss; solar
	photosensitivity; hyponatremia;
	sexual dysfunction (both
	genders); may alter glycemic
	control in diabetic patients.

The second way is to stretch the normal rows vertically, such that they fit with the multirow entry. In this table, where the font size is 10pt, each row has a total height of 12pt. For the first entry we need 24pt extra (2 rows), Because this space must be divided over 3 rows that is 8pt per row, making the total height of the row 20pt. The normal row has a height of 8.4pt and a depth of 3.6pt (total 12pt). We can add 4pt on the top and 4pt on the bottom, or any other combination that adds up to 8pt. In this case I have chosen to make the height 12pt and the depth 8pt. We do this with a \rule with 0 width. \newcommand{\mystrut}{\rule[-8pt]{0pt}{20pt}} and put \mystrut in each of the first 3 rows. By defining your own struts you have complete control over the layout. You can choose to give some rows more space than others, or to put all the space is the last row, for example.

For the second entry we need 48pt extra (4 rows). We will use \bigstrut in each row, that is 16pt per row, and as a \bigstrut is 2\bigstrutjots, we set \bigstrutjot to 8pt. The booktabs package adds some extra vertical space around the rules, therefore when using the normal tabular environment, it is probably better to make the struts a little bit bigger, or a bit smaller with booktabs. After some experimentation it appeared that a \bigstrutjot of 7pt was enough. Of course we added the $\langle bigstruts \rangle$ parameter of [tb6] to the second multirow. Please note that this is not possible with our own struts, unless we cheat.

Now with **booktabs** the code becomes:

\mystrut

```
& initial: 200 mg/day \mystrut & \\
cmidrule(r){1-2}
    & maintenance: 100-400 mg/day \mystrut & \\
\midrule
\multicolumn{2}{l}{Conzac} \bigstrut
                     & \multirow{3}[tb6]={Anxiety; nervousness;
                      insomnia; anorexia; mild bradycardia;
                      SA node slowing; weight loss;
                      solar photosensitivity; hyponatremia;
                      sexual dysfunction (both genders); may
                      alter glycemic control in diabetic patients.} \\
cmidrule(r){1-2}
  & initial: 10 mg/day \bigstrut & \\
cmidrule(r){1-2}
  & maintenance: 10-40 mg/day \bigstrut & \\
\bottomrule
\end{tabular}
```

Medicine & dose	Possible Side effects
Spirino	Confusion, hallucinations, rapid breathing, seizure (convulsions);
initial: 200 mg/day	upset stomach, heartburn; severe nausea, vomiting, or
maintenance: 100-400 mg/day	stomach pain or mild headache.
Conzac	Anxiety; nervousness; insomnia; anorexia; mild bradycardia; SA
initial: 10 mg/day	node slowing; weight loss; solar photosensitivity; hyponatremia; sexual dysfunction (both
maintenance: 10-40 mg/day	genders); may alter glycemic control in diabetic patients.

4 Using bigstrut

\bigstrut \bigstrutjot $\bigstrut[\langle x \rangle]$ produces a strut (a rule with width 0) which is \bigstrutjot (2pt by default) higher, lower, or both than the standard array/tabular strut. Use it in table entries that are adjacent to \bigstrut to leave an extra bit of space — according to the TeXbook (page 246), "This is a little touch that improves the appearance of boxed tables; look for it as a mark of quality."

Although you could use \bigstrut in an array, there isn't normally much point since arrays are 'opened up' by \jot anyway.

\bigstrut[t] adds height; \bigstrut[b] adds depth. Just \bigstrut adds both. So: Use \bigstrut[t] in the row just *after* an \hline; \bigstrut[b] in the row just *before*; and \bigstrut if there are \hlines both before and after.

Spaces after the \bigstrut are ignored, even if it has an optional parameter. Spaces before the \bigstrut are generally ignored (by a single \unskip).

Note: The multirow package makes use of \bigstrutjot. If both packages are used, they can be used in either order, as each checks to see if the other has

\bigstrutjot

already defined \bigstrutjot. However, the default values they set are different: if only multirow is used, \bigstrutjot will be set to 3pt. If bigstrut is used, with or without multirow, \bigstrutjot will be 2pt.

$\mathbf{5}$ Using bigdelim

Syntax of use is

The package is for working in a tabular or array environment, in which the multirow package is also used.

\ldelim \rdelim

 $\forall delim (\{ \langle n \rangle \} \{ \langle width \rangle \} [\langle text \rangle]$ $\tau = \frac{\langle n \rangle}{\langle width \rangle} [\langle text \rangle]$

The commands are used in a column of a tabular or array; they create a big parenthesis, brace or whatever delimiter that extends over the $\langle n \rangle$ rows starting at the one containing the command. Corresponding cells in the following rows must be explicitly given as empty cells.

The first parameter is a delimiter to be used, e.g., $\{ \} [] () - in fact,$ anything that can be used with \left or \right, as appropriate.

Here is an example:

```
\begin{equation}
 \begin{array}{cccccc}
   \ldelim({4}{4mm} & x & x & x & x & \rdelim){4}{4mm} \\
   & x & x & x & x & & i \\
   & x & x & x & x & & j \\
   %x & x & x & x & \\
   & & u & v &
 \end{array}
\end{equation}
```

(1)

When $\forall delim is used$, the optional $\langle text \rangle$ is set centred to the left of $\forall delim$. If $\forall rdelim$ is used it is set to the right of $\forall rdelim$. The $\langle width \rangle$ parameter is the space that is reserved for the delimiter and its text; as with the multirow package, the $\langle width \rangle$ may be given as *. Compare for example these:

\begin{tabular}{p{2em}1} \ldelim\{{3}{*}[type] & dvi \\

\end{tabular}

In the first example we cheated: by using a column width that is too small, we swallowed up some of the intercolumn space, at the cost of an "Overfull hbox" message. In the second example we did it the proper way by inserting $O{\{,\}}$ to replace the default intercolumn space with a narrow space.

Also the commands may be used in the last row of the extension with a negative $\langle n \rangle$ parameter. This is useful in combination with colortbl (see the discussion in section 3 on multirow). If there are unusually tall rows you may have to enlarge $\langle n \rangle$ (you can use non-integral values). If you have horizontal lines that interact with the braces you are advised to use the hhline package to make the lines.

In case you want to have a paragraph type text as optional parameter you could put it in a **\parbox**. Alternatively you could add an extra column with the text in a **\multirow**, like in

```
\begin{tabular}{1@{}1@{}1}
  dvi & \rdelim\}{3}{1em} & \multirow{3}{4cm}{These are the output types,
        that are commonly used for \TeX.} \\
   ps & & & \\
   pdf & & \\
\end{tabular}
```

Note that we used $@{}$ to eliminate the intercolumn space to get the text tight to the brace.

6 Implementation

6.1 The multirow package

This is a boolean to [de]activate debugging (showing the generated box contents). It is activated by the **debug** package option. The **\newif** initializes it to false.

```
e 1\newif\ifmultirowdebug
```

```
\label{eq:local_local_state} 2 \label{multirowdebugtrue} \label{multirowdebugtrue} 2 \label{multirowdebugtrue}
```

```
\cline The package option longtable redefines the \cline macro to work around a bug in longtable. See section 3.5^2.
```

```
3 \DeclareOption{longtable}{%
```

```
4 \AtBeginDocument{%
```

```
5 \def\@cline#1-#2\@nil{%
6 \omit
```

```
(OILT C
```

\ifmultirowdebug
\multirowdebugtrue
\multirowdebugfalse

 $^{^2} Thanks to David Carlisle. See http://tex.stackexchange.com/questions/52100/longtable-multirow-problem-with-cline-and-nopagebreak#answer-52101$

\multirow@setcolwidth	This macro calculates $\multirow@colwidth$ for an entry that has the $\langle width \rangle$ given as "=". We check if we are inside a tabulary environment, by checking if $\TY@final$ is defined. If not, then $\multirow@colwidth = \hsize$. The tabulary environment will make two passes. On the first pass, we set $\multirow@colwidth$ to the size that the text would have in LR mode (with newlines replaced by spaces), so that tabulary will gives us enough space. On the second pass (characterized by $\TY@box = \TY@box@v$) we use the value that tabulary has given us in \hsize . This algorithm is not perfect, but good enough in most cases.
	<pre>61 \def\multirow@setcolwidth#1{% 62 \ifx\TY@final\@undefined \multirow@colwidth=\hsize 63 \else 64 \ifx\TY@box@v\multirow@colwidth=\hsize 65 \else \setbox0\hbox 66 {\let\\\space\let\newline\space #1}\multirow@colwidth=\wd0 67 \fi 68 \fi}</pre>
\multirowsetup	<pre>\multirowsetup is executed at the beginning of each \multirow. 69 \newcommand\multirowsetup{\raggedright}</pre>
\multirow@vbox	This creates the $\forall vbox$. Parameters: #1 = $\langle vpos \rangle$, #2 = initialization code (for example to set the width of the $\forall parbox$), #3 = box contents. Depending on the $\langle vpos \rangle$ parameter, it will be top-aligned, vertically centered, or bottom-aligned. This is done by inserting $\forall rill$ in the proper places. Note: the \relax is to protect against an empty $\langle vpos \rangle$ parameter.

```
70 \long\def\multirow@vbox#1#2#3{\setbox0\vtop to \multirow@dima{#2%

The text is set in a \vbox by calling \multirow@vbox.

```
If the \langle width \rangle parameter is * set just the text in the \vbox.
```

96 \if*#4\multirow@vbox{#1}{}{\hbox{\strut#6\strut}}%

Otherwise set it in a \parbox inside a \vbox.

If the $\langle width \rangle$ parameter is given as "=", we calculate \multirow@colwidth and use that as width of the \parbox.

97 \else \if=#4\multirow@setcolwidth{#6}%

```
98 \multirow@vbox{#1}{\hsize\multirow@colwidth\@parboxrestore}{\strut#6\strut\par}%
Otherwise the given parameter is used as the width of the \parbox.
```

```
99 \else \multirow@vbox{#1}{\hsize#4\@parboxrestore}{\strut#6\strut\par}%
100 \fi \fi
```

Now position the vbox properly. More details are given in the appendix. The overview of the calculation of the shift amount can be found in section A.3.

```
If \langle nrows \rangle > 0:
```

If $\langle vpos \rangle = [t]$, then the box is already positioned correctly (the baseline is on the baseline of the row). However, later the top of the box will be taken as the reference point (instead of the baseline), therefore we take the height of the box (h) as the shift amount. See fig. 1.

If $\langle vpos \rangle = [c]$ we shift it up h1 (see fig. 2), where h1 = $ht\0$ arstrutbox + (\bigstrutjot \ifmultirow@prefixt).

If $\langle vpos \rangle = [b]$ we shift it up h1 + h2 (see fig. 3), where h2 = \dp\@arstrutbox + (\bigstrutjot \ifmultirow@prefixb).

We calculate the required shift in \multirow@dima.

```

- 137 {\left.\vcenter{\hsize=Opt\vrule height \multirow@dima width Opt}%
- 138 \textrm{#4}\right#1}}

\rdelim This macro typesets a right delimiter. It calls \multirow with the proper parameters, similar to \ldelim.

```
139 \newcommand\rdelim[3]{\@ifnextchar[{\@rdelim{#1}{#2}{#3}}{\@rdelim{#1}{#2}{#3}[\null]}}
140 \def\@rdelim#1#2#3[#4]%
141 {\multirow{#2}{#3}{%
142 \ensuremath
143 {\left#1\vcenter{\hsize=0pt\vrule height \multirow@dima width 0pt}%
```

144 \textrm{#4}\right.}}

A Appendix

In this section we explain the νvox positioning in μvox . The positioning depends on the $\langle nrows \rangle$, $\langle vpos \rangle$, $\langle bigstruts \rangle$ and $\langle vmove \rangle$ parameters. The box is constructed with νvop . The algorithm of νvop is described in *The TEXbook*, p. 81.

Each case is described by a figure. In the figure the lefthand column indicates the context of the tabular in which the multirow appears, i.e $\langle nrows \rangle$ rows. The righthand column is the multirow box that is to be inserted. The baseline is the natural position where the material will be positioned in the first place. Later it will be shifted up to the desired location.

H is the calculated height of the box: $\langle nrows \rangle \times$ the natural height of a row + $\langle bigstruts \rangle \times \langle bigstrutjot.$

topstrut = \bigstrutjot if there is a \bigstrut on the top of the first row (as indicated by the t prefix in the $\langle bigstruts \rangle$ parameter), otherwise 0.

botstrut = \bigstrutjot if there is a \bigstrut on bottom of the last row (as indicated by the b prefix in the $\langle bigstruts \rangle$ parameter), otherwise 0.

h1 = height of a tabular row + topstrut

h2 = depth of a tabular row + botstrut

Note: the following descriptions describe the vertical shift of the box without taking the $\langle vmove \rangle$ into account. In all cases $\langle vmove \rangle$ has to be added if it is given.

A.1 Case $\langle nrows \rangle > 0$

 $\langle vpos \rangle = [t]$

Alternatively, we could have omitted the **\vskip** in this case, thereby leaving the baseline undisturbed, but this would make the code unsymmetrical. Moreover, this would not work when a non-zero $\langle vmove \rangle$ is present. Therefore we choose to set the shift amount to h here.

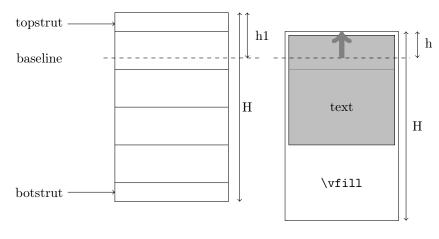

Figure 1: Case $\langle nrows \rangle > 0$, $\langle vpos \rangle = [t]$

$\langle vpos \rangle = [c]$

In this case the $\forall vbox$ contains a $\forall rill$, the text, and another $\forall rill$. Such a $\forall vbox$ has a height 0, i.e. the top of the box is on the baseline. Because both boxes have the same size (H), they can be aligned by shifting the $\forall vbox$ up over h1. See fig. 2.

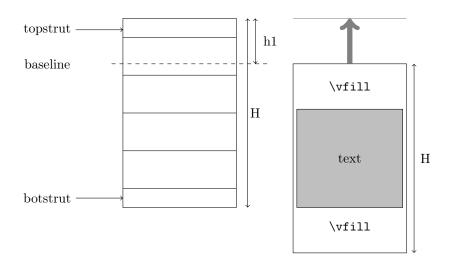

Figure 2: Case $\langle nrows \rangle > 0$, $\langle vpos \rangle = [c]$

$\langle vpos \rangle = [b]$

Now the $\forall vbox$ contains a $\forall vfill$, followed by the text. Because it ends with the text, it gets an additional depth equal to the depth of the last line of the text. Such a $\forall vbox$ has a height 0, i.e. the top of the box is on the baseline, but its depth is H + that depth. In other words the baseline of the last text line is H below the top.

Because $\langle vpos \rangle = [b]$ we want the baseline of the last textline to shift to the baseline of the last tabular row. The amount of the shift is h1 + h2. See fig. 3.

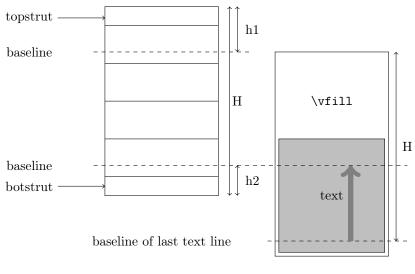

Figure 3: Case $\langle nrows \rangle > 0$, $\langle vpos \rangle = [b]$

A.2 Case $\langle nrows \rangle < 0$

 $\langle nrows \rangle < 0$ when the multirow is positioned in the last row of the multirow block.

$\langle vpos \rangle = [t]$

In this case the \vbox contains the text followed by a \vfill. Such a \vbox has a height that is the height of the top line of the text. The baseline is aligned with the baseline of the last row. Because $\langle vpos \rangle = [t]$, we want it to be aligned with the baseline of the first row. Therefore it has to be shifted up H - h1 - h2. But because later the height of the box will be set to 0, we must also add the current height h. Therefore the total shift becomes H - h1 - h2 + h. See fig. 4.

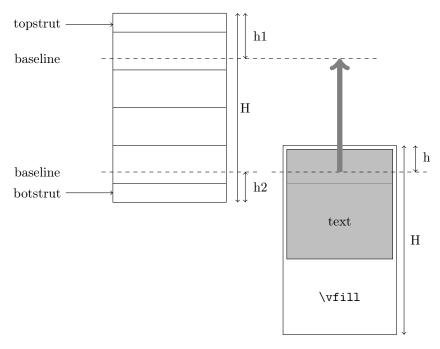

Figure 4: Case $\langle nrows \rangle < 0$, $\langle vpos \rangle = [t]$

$\langle \textit{vpos} angle = [c]$

In this case the νbox contains a $\nu fill$, the text, and another $\nu fill$. Such a νbox has a height 0, i.e. the top of the box is on the baseline. Because both boxes have the same size (H), they can be aligned by shifting the νbox up over H - h2. See fig. 5.

$\langle vpos \rangle = [b]$

The $\forall vbox contains a \forall vfill, followed by the text. Because it ends with the text, it gets an additional depth equal to the depth of the last line of the text. Such a <math>\forall vbox has a height 0$, i.e. the top of the box is on the baseline, but its depth is H + that depth. In other words the baseline of the last text line is H below the top.

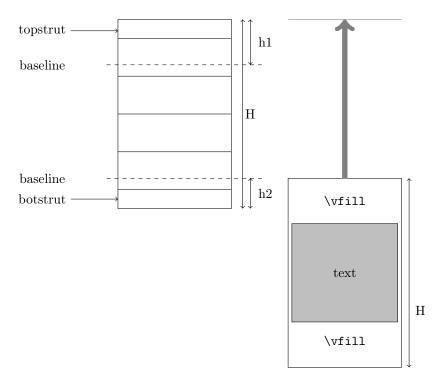

Figure 5: Case $\langle nrows \rangle < 0$, $\langle vpos \rangle = [c]$

Because $\langle vpos \rangle = [b]$ we want the baseline of the last textline to shift to the baseline of the last tabular row. The amount of the shift is H. See fig. 6.

A.3 Overview

$\langle vpos \rangle$	$\langle nrows angle > 0$	$\langle nrows angle < 0$
[t]	h	H-h1-h2+h
[c]	h1	H - h2
[b]	h1 + h2	Н
	х	$\mathbf{H} - \mathbf{h}1 - \mathbf{h}2 + x$
