

Version 0.6

# Ahmed Musa⊠ Preston, Lancashire, UK

29th April 2010

# Abstract

This package supplements the xkeyval package. It introduces toggle keys and complementary (bipolar and unipolar) native-boolean and toggle-boolean keys. It also provides mechanisms for reserving, unreserving, suspending, restoring, and removing keys. Furthermore, it introduces a set of commands for key definition which bar the developer or user from inadvertently redefining existing keys of the same family and prefix. Commands are provided for checking the statuses of keys across multiple key prefixes and families. Also, the package provides a scheme for defining multiple keys of different genres using only one command, thereby making it possible to considerably economize on tokens when defining keys. The package introduces the notion of "user-value keys" and provides facilities for managing those keys. The pointer mechanisms of the xkeyval, which were only available at key setting time, are now invocable at key definition. Some other general-purpose developer macros and hooks are provided by the package.

## LICENSE

This work (i.e., all the files in the skeyval bundle) may be distributed and/or modified under the conditions of the IATEX Project Public License (LPPL), either version 1.3 of this license or any later version.

The  $IAT_{EX}$  Project Public License maintenance status of this software is "authormaintained". This software is provided "as it is," without warranty of any kind, either expressed or implied, including, but not limited to, the implied warranties of merchantability and fitness for a particular purpose.

The package is now at open beta stage and package distributors are advised to wait for at least a stable version 1.0 before embarking on distribution. Bug reports and suggestions to improve the package are particularly welcome. Correspondents should use the file skeyval-bugreport.tex, provided as part of the bundle, to report bugs. © MMX

 $<sup>^{\</sup>diamond} The$  skeyval package was formerly called the keyreader package until version 0.5. The keyreader is now obsolete and no longer supported.

<sup>\*</sup>The package is available at http://www.ctan.org/tex-archive/macros/latex/contrib/ skeyval/.

# 1 MOTIVATION

 $\fbox Oggle switches or booleans were introduced by the etoolbox package and have proved attractive mainly for two reasons: unlike the legacy/native <math display="inline">T_E\!X$  switches which require three commands per switch, toggles require only one command per switch, and toggles occupy their own separate namespace, thereby avoiding clashes with other macros. So we can effectively have both the following sets in the same file:

```
<sup>3</sup> \ifmyboolean \mybooleantrue
\mybooleanfalse
5 % Toggle switch:
6 \newtog{myboolean} → only 1 command and no clash with
commands in other namespaces.
```

**Note:** A toggle is also a boolean or switch. We refer to it here as *toggle* or *toggle switch* or *toggle boolean*. The term *Knuth/native switch* is reserved here for  $T_EX$ 's legacy boolean or switch.

The xkeyval package can't be used to define and set toggle keys. The present package provides facilities for defining and setting toggle keys. The work relies on some of the macros from the xkeyval package.

Secondly, the xkeyval package can't be used to define and set complementary (bipolar and unipolar) keys, which can be handy in the case of native boolean and toggle keys. Complementary bipolar keys are mutually exclusive keys, i.e., they never assume the same state of a two-valued logic, and they switch states automatically, depending on the state of any one of them. So whenever one of them assumes one of the two states of a two-valued logic, the other one automatically switches its state from whatever state it was previously, such that the two are never in the same state. Simple examples of complementary bipolar keys would be the options draft and final in a document; they are mutually exclusive. Complementary bipolar keys carry equal charge, i.e., each one can equally toggle the other with identical propensity, but the one that represents the default state of a two-valued logic is usually considered the primary, while the other is secondary. In many document classes, for instance, final is considered a default document option and draft would have to be explicitly selected by the user to toggle final to false.

Complementary unipolar keys, on the other hand, are mutually inclusive, i.e., both are always in the same state of a two-valued logic: when one is switched to a particular state, the complement too is automatically toggled to the same state. An example of complementary unipolar keys would be the options hyperref and microtype in a package or class file. When hyperref package is loaded, we may want microtype package loaded as well, and vice versa. Complementary unipolar keys, like bipolar keys, also carry equal charge, i.e., one can toggle the other with equal propensity, but to the same state for the two keys. For a pair of unipolar keys, the primary key is the one that is associated with the default state.

The present package introduces these concepts of bipolar and unipolar keys and additionally permits the submission of individual/different custom key macros to complementary (bipolar and unipolar) native boolean and toggle keys. Biunipolar keys are introduced as well.

The third motivation for this package relates to economy of tokens in style files. The xkeyval package provides \define@cmdkeys and \define@boolkeys for defining and setting multiple command keys and boolean keys, but in each category the keys must have the same default value and no key macro/function. This package seeks to lift these restrictions, so that multiple keys of all categories (ordinary keys, command keys, boolean keys, tog keys, and choice/menu keys) can be defined in one go (using only one command) and those keys can have different default values and functions. This greatly minimizes tokens, as hundreds of keys can, in principle, be issued simultaneously by one command.

Fourthly, macros are introduced for defining all key types without the fear of inadvertently redefining existing keys in the same family and with the same key prefix. This has a philosophy similar to the  $\mbox{newcommand}$  concept in LATEX.

The package also provides facilities for disabling, suspending, restoring and removing keys across multiple families of keys. The pointer system of the xkeyval package is also extended by the skeyval package, and the notion of "user-value" keys is introduced.

The new macros can be used together with the machinery from the xkeyval package for efficient and versatile key management.

# 2 BRACE STRIPPING BY THE XKEYVAL PACKAGE

The xkeyval package strips off up to three levels of braces in the value part of the key-value pair: one by using the keyval package's leading and trailing space removal command and two in internal parsings (at some known commands). The keyval strips off only two levels of braces: one in using its space removal routine and one in internal parsings. The kvsetkeys package strips off only one level of braces. The matter of these differences has not yet been shown to have serious implications for existing or new packages, although it is apparently of concern to the keycommand package.

The skeyval package internally uses a space removal scheme that doesn't strip off braces from its arguments, but since the present package relies, to a good extent, on the engine of the xkeyval package, the brace stripping effect has remained.\* It can easily be solved but there is currently no sufficient reason to do so. If, odd enough, you want at least one level of braces to persist in the value part of the key-value pair throughout parsing, you simply surround the value with four levels of braces in the \setkeys command. If the users of this, or the xkeyval package, feel that this issue is of significant concern, then it can be addressed in the future.

#### 3 THE SKEYVAL PACKAGE OPTIONS

The package can be loaded in style and class files by

```
Example
```

\RequirePackage[options]{skeyval}

and in document files via

<sup>\*</sup>We have had to redefine some of the internal macros of the xkeyval package, but getting rid of the brace-stripping issue would require even more substantial revision of the internal macros of the xkeyval package.

```
\usepackage[options]{skeyval}
```

keyfamily=fam}

where the user options and their default values are

```
Macro
```

Example

```
keyparser=;, macroprefix=mp@, keyprefix=KV, keyfamily=fam,
10
     verbose=false
11
```

The  $\langle keyparser \rangle$  is the separator between the keys in the key list to be defined in one go (see Subsection 7.2). The (macroprefix), (keyprefix), and (keyfamily) are, respectively, the macro prefix, key prefix and key family for all the keys to be defined upon the declaration of these options. All these options can be set or changed dynamically by using the \skvoptions macro:

Macro

```
12
13
```

These options are explained in more detail in subsequent sections.

\skvoptions{keyparser=;, macroprefix=mp@, keyprefix=KV,

If, as unlikely as it may seem, a clash arises between package and/or user macros as a result of the use of the defaults for (macroprefix), (keyprefix) and (keyfamily), then the user will have to make his own choices for these defaults so as to avoid clashes.

The skeyval package issues a fatal error if it is loaded before (or run without) \documentclass.

#### 4 COMPLEMENTARY NATIVE-BOOLEAN KEYS

# 4.1 Bipolar native-boolean keys

As mentioned in Section 1, complementary bipolar keys are keys that depend inversely on each other: when one of them is in a particular state of a two-valued logic, the other one automatically assumes the opposite or complementary state. For each pair of bipolar keys, one is normally assumed to be the primary key and the other the secondary. The primary boolean key will usually represent the default state of a two-valued logic. Whenever one bipolar key (primary or secondary) is true, its complement is automatically set false; and vice versa: when one bipolar key (primary or secondary) is false, its complement is automatically set true. Generally, the transition of the state of a key from negative (false) to positive (true) is associated with the execution of the key's macro.

The syntax for creating bipolar native-boolean keys is

```
Macro
```

14 15 \define@biboolkeys[{keyprefix}]{{family}}[{macroprefix}] {\primary boolean}][\default value for primary boolean ]]

17

18

19

20

```
{\secondary boolean\}{\func for primary boolean\}
{\func for secondary boolean\}
```

This command is robust and can be used in expansion contexts, but expandable commands may need to be protected. When the user doesn't supply the  $\langle keyprefix \rangle$  and/or  $\langle macroprefix \rangle$ , the package will use  $\langle KV \rangle$  and  $\langle mp@ \rangle$ , respectively. When the default value for the primary boolean is not supplied, the package will use true. Infinite loops, which are possible in back-linked key settings, are avoided in the skeyval package. The machinery of the xkeyval package, such as stkeys, presetkeys, savekeys, savevalue, usevalue, etc., are all applicable to complementary bipolar keys.

As an example, we define below two bipolar native-boolean keys  $\langle draft \rangle$  and  $\langle final \rangle$  with different key macros:

```
      Example

      \define@biboolkeys[KV]{fam}[mp@]{draft}[true]{final}%

      {\def\noneofone##1{}}{\def\oneofone##1{##1}}
```

The key prefix (default KV), macro prefix (default mp@), key macros (no default), and the default value of the primary boolean (true) can all be empty:

Example

\define@biboolkeys{fam}{draft}{final}{}}.

\setkeys[KV]{fam}{draft=true,final=true}.

The defined complementary bipolar keys  $\langle draft \rangle$  and  $\langle final \rangle$  can now be set separately as follows:

```
      Example

      21
      \setkeys[KV]{fam}{draft=true}

      22
      \setkeys[KV]{fam}{final=true}
```

The second statement above reverses the boolean  $\langle draft \rangle$  to  $\langle false \rangle$ , which had been set in the first statement to  $\langle true \rangle$ . There is no apparent meaning to the following:

Example

23

### 4.2 Unipolar native-boolean keys

Unipolar boolean keys are two keys that are always in the same state: when one is true (or false), the other one is also true (or false). In this regard, the key macro is always executed when a key transits to the "true" state. The syntax for creating unipolar native-boolean keys is exactly as that for defining bipolar native-boolean keys:

29

30

33

```
Macro
                                                                                                                                              \det \left[ \langle e_1 \rangle \right] \left[ \langle e_2 \rangle \right
24
                                                                                                                                                                                          {\primary boolean}][\default value for primary boolean ]]
25
                                                                                                                                                                                          {secondary boolean}}{func for primary boolean}}
26
                                                                                                                                                                                              \{ \langle func for secondary boolean \rangle \}
   27
```

This command is robust and can be used in expansion contexts, but expandable commands may need to be protected. Again, if the user doesn't supply the (keyprefix) and/or (macroprefix), the package will use (KV) and (mp@), respectively. When the default value for the primary boolean is not supplied, the package will assume it to be true.

The following example constructs two unipolar boolean keys:

```
Example
\define@uniboolkeys[KV]{fam}[mp@]{pdfmode}[true]{microtype}%
{\temptoks{Yes, in 'pdfmode'}}{\def\temp{'microtype' loaded}}
```

## 4.3 Biunipolar native-boolean keys

Biunipolar keys are the generalized forms of bipolar and unipolar boolean keys, with one important restriction: unlike bipolar and unipolar keys, biunipolar keys have no symmetrical relationships. That is to say that the relationship between a pair of biunipolar keys is entirely determined by the primary key. A pair of biunipolar boolean keys possess only one of the following four types of relationship:

- a) Unipolar property: When the primary key is false, it sets the secondary key to false ( $\star$  +-form of biunipolar keys). The secondary key macro isn't executed.
- b) Bipolar property: When the primary key is false, it sets the secondary key to true ( $\star$ -form). The secondary key macro is executed.
- c) Bipolar property: When the primary key is true, it sets the secondary key to false (+-form). The secondary key macro isn't executed.
- d) Unipolar property: When the primary key is true, it sets the secondary key to true (unsigned form). The secondary key macro is executed.

Of course, the primary key can be true only after it has been set.

The syntax for establishing biuni boolean keys is exactly like that for creating other complementary boolean keys, except for the optional  $\star$  and + signs:

```
Macro
```

```
\det \left( \frac{1}{2} + \frac{1}{2} + \frac{1}{2} \right) 
       {\primary boolean}][\default value for primary boolean ]]
31
       {secondary boolean}}{macro for primary boolean}}
32
       \{(macro for secondary boolean)\}
```

As an example, consider the arbitrary package or class options review and preprint. The option preprint can automatically toggle review to true, but possibly not vice versa: not every preprint is a manuscript for review. This is depicted below:

```
Example
     \define@biuniboolkeys[KV]{fam}[mp@]{preprint}[true]{review}{}{%
34
       \ifmp@review
35
          \SKV@BeforeDocumentStart{%
36
            \linespread{1.5}\selectfont
37
            \def\banner{\fbox{\textit{This is a review document}}}%
38
          }%
39
        \else
40
          \SKV@BeforeDocumentStart{\let\banner\@empty}%
41
       \fi
42
     }
43
```

As another example, consider the following biuni keys, each with its own macro:

```
Example
      \define@biuniboolkeys*+[KV]{fam}[mp@]{brother}[true]{sister}{%
44
        \ifmp@brother
45
          \def\mybrother{Hamilton}%
46
       \fi
47
     }{%
48
        \ifmp@sister
49
          \SKV@AfterDocumentStart{\def\mysister{Kate}}%
50
        \else
51
          \SKV@AfterDocumentStart{\let\mysister\@gobble}%
52
        \fi
53
     }
54
     \setkeys[KV]{fam}{brother=true}
55
```

# 5 Toggle booleans and keys

In the following Subsections 5.1 to 5.2 we define toggle booleans/switches and use them to introduce toggle-boolean keys.

## 5.1 Toggle booleans

The following toggle switches are defined in the skeyval package. They largely mimic those in the etoolbox package, except for the commands \deftog and \requiretog. There is no fear that the commands in this package will interfere with those from the etoolbox package, since the internal control sequences and user interfaces of the two packages are different.

All the commands in this section are robust and can be used in expansion or moving contexts, but fragile arguments would need to be protected in those settings.

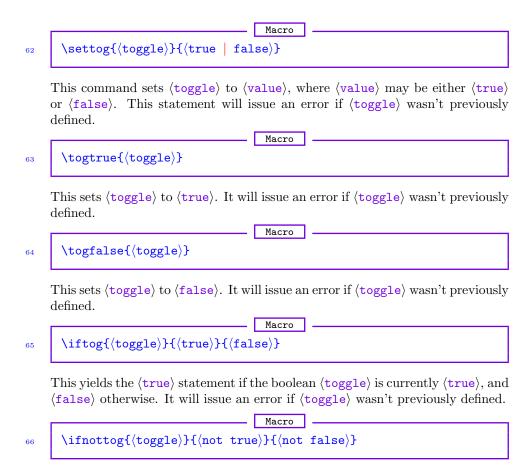

# Macro $deftog{(toggle)}$ 56 This defines a new $\langle toggle \rangle$ whether or not $\langle toggle \rangle$ is already defined. If (toggle) is already defined, a warning message is logged in the transcript file (if the package option verbose is selected) and the new definition is effected. Macro $\ensuremath{newtog}{\langle toggle \rangle}$ 57 This defines a new $\langle toggle \rangle$ if $\langle toggle \rangle$ is not already defined; otherwise the package issues a fatal error. You can define a set of toggles by the following command: Macro \NewTogs[(optional prefix)]{(toggles)}[(optional state)], 58 where $\langle toggles \rangle$ is a comma-separated list. Each member of $\langle toggles \rangle$ is prefixed with (prefix) upon definition. The optional (state) can be either true or false. For example, we may define new toggles x, y, z by the following: Example $\ \[skv@]{x,y,z}[true]$ 59 Macro $providetog{(toggle)}$ 60 This defines a new $\langle toggle \rangle$ if $\langle toggle \rangle$ is not already defined. If $\langle toggle \rangle$ is already defined, the command does nothing.

61

Macro

\requiretog{(toggle)}

The skeyval package also provides the command \requirecmd, which has the same logic as \requiretog but can be used for general  $\text{LAT}_{\text{E}}X$  commands, including those with optional arguments (see Section 13).

This behaves like iftog but reverses the logic of the test. It will issue an error if  $\langle toggle \rangle$  wasn't previously defined.

# 5.2 Toggle-boolean keys

The user interfaces for defining toggle-boolean keys is exactly like those for native-boolean keys in the xkeyval package. This allows all the machinery of the xkeyval package (including \setkeys, \presetkeys, \savekeys, \savevalue, \usevalue, etc) to be applicable to toggle-boolean keys.

As mentioned earlier, toggles have their own separate namespace. However, the \setkeys command (and friends) of the xkeyval package is unaware of this. This can cause problems when the user uses the same name for native-boolean and toggle keys (or indeed any key type) in the same family and with the same key prefix, believing rightly that toggle keys have their own separate namespace. If this is a source of significant concern to any user, he will be well advised to instead use the commands \newboolkey, \newboolkeys, \newtogkeys, \newtogkeys, etc., of Subsection 8.2. In those commands a mechanism is included to bar keys from having the same name as other keys in the same family and with the same prefix. Toggle keys can still share the same names with keys across families and key prefixes. Since it is not always certain which of the keys the user may want to first define (before its definition is possibly repeated),

the fear of interference has necessitated new syntaxes for defining all key types, which completely avoid interference (see Subsection 8.2).

The user interfaces for defining toggle keys are

 Macro

 67
 \define@togkey[{prefix}]{{family}}[{mp}]{{key}}[{default}]%

 68
 {{function}}

 69
 \define@togkey+[{prefix}]{{family}}[{mp}]{{key}}[{default}]%

 70
 {{function1}}{{function2}}

If the macro prefix  $\langle mp \rangle$  is not specified, these create a toggle of the form  $\langle prefix \rangle @\langle family \rangle @\langle key \rangle$  using  $\langle deftog \rangle$  (which initializes the toggle switch to false) and a key macro of the form  $\langle prefix \rangle @\langle family \rangle @\langle key \rangle$  which first checks the validity of the user input. If the value is valid, it uses it to set the toggle and then executes  $\langle function \rangle$ . If the user input wasn't valid (i.e., neither true nor false), then the toggle will not be set and the package will generate a fatal error to this effect.

If  $\langle mp \rangle$  is specified, then the key definition process will create a toggle of the form  $\langle mp \rangle \langle key \rangle$  and a key macro of the form  $\langle mp \rangle \langle key \rangle$ . The value  $\langle default \rangle$  will be used by the key macro when the user sets the key without a value.

If the plus (+) version of the macro is used, the user can specify two key macros  $\langle \text{function1} \rangle$  and  $\langle \text{function2} \rangle$ . If user input is valid, the macro will set the toggle and executes  $\langle \text{function1} \rangle$ ; otherwise, it will not set the boolean but will execute  $\langle \text{function2} \rangle$ .

As an example, consider the following:

```
Example
      \define@togkey{fam}[my@]{frame}{%
71
        \iftog{my@frame}{%
\mathbf{72}
          \PackageInfo{mypack}{Turning frames on}%
73
        }{%
74
          \PackageInfo{mypack}{Turning frames off}%
75
        }%
76
     }
77
     \define@togkey+{fam}{shadow}{%
78
        \iftog{KV@fam@shadow}{%
79
          \PackageInfo{mypack}{Turning shadows on}%
80
        }{%
81
          \PackageInfo{mypack}{Turning shadows off}%
82
        }%
83
     }{%
84
          \PackageWarning{mypack}{Erroneous input '#1' ignored}%
85
     }
86
```

The first example creates the toggle  $\langle my@frame \rangle$  and defines the key macro KV@fam@frame to set the boolean (if the input is valid). The second key in-

timates the user of changed settings, or produces a warning when input was incorrect.

It is also possible to define multiple toggle keys with a single command:

```
Macro
\ensuremath{\label{eq:log_log_log_log_log_l}} \
```

This creates a toggle key for every entry in the comma-separated list  $\langle keys \rangle$ . As is the case with the commands \define@cmdkeys and \define@boolkeys from the xkeyval package, the individual keys in this case can't have a custom function. See Section 7 for how to define multiple keys with custom functions.

Example

Example

As an example of defining multiple toggle keys, consider

```
88
```

```
\define@togkeys{fam}[my@]{toga,togb,togc}
```

This is an abbreviation for

\define@togkey{fam}[my@]{toga}{} 89 \define@togkey{fam}[my@]{togb}{} 90 \define@togkey{fam}[my@]{togc}{} 91

Now we can do

```
Example
```

```
\define@togkey{fam}[my@]{book}{%
92
       \iftog{my@book}{\setkeys[KV]{fam}{togc=true}}{}%
93
94
     \setkeys[KV]{fam}{book=true}
95
```

Toggle keys can be set in the same way that other key types are set.

The status of toggles can be examined by doing

when the  $\langle mp \rangle$  is present. When the user has specified no  $\langle mp \rangle$  in defining the key, he has to issue

Example

```
97
```

96

```
Example
```

#### 6 COMPLEMENTARY TOGGLE KEYS

## 6.1 Bipolar toggle-boolean keys

Similar to complementary native-boolean keys of Section 4, the skeyval package introduces facilities for creating complementary (bipolar, unipolar and biunipolar) toggle keys. The syntax for defining bipolar toggle keys is identical to that for defining bipolar native-boolean keys:

```
      Macro

      98
      \define@bitogkeys[\leftakeyprefix\rightarrow] {\leftamily\rightarrow}] {\leftamily\rig\rig\rightarrow}] {\leftamily\rig\rightarrow}]
```

This command is robust and can be used in expansion contexts, but non-robust commands have to be protected. When the user doesn't supply the  $\langle keyprefix \rangle$  and/or  $\langle macroprefix \rangle$ , the package will use  $\langle KV \rangle$  and  $\langle mp@ \rangle$ , respectively. When the default value for the primary toggle-boolean is not supplied, the package will use true. When one of the bipolar toggle keys (primary or secondary) is true, the other is automatically set false; and vice versa: when one toggle key (primary or secondary) is false, the other is automatically set true.

As an example, we define below two bipolar toggle keys  $\langle xdraft \rangle$  and  $\langle xfinal \rangle$  with different key macros:

```
        Example

        102
        \define@bitogkeys[KV]{fam}[mp@]{xdraft}[true]{xfinal}%

        103
        {\def\gobble##1{}}{\def\firstofone##1{##1}}
```

The key prefix (default KV), macro prefix (default mp@), key macros (no default), and the default value of the primary boolean (default true) can all be empty:

Example

104

105

106

\define@bitogkeys{fam}{xdraft}{xfinal}{}}.

The defined bipolar toggle keys  $\langle xdraft \rangle$  and  $\langle xfinal \rangle$  can now be set as follows:

```
      Example

      \setkeys[KV]{fam}{xdraft=true}

      \setkeys[KV]{fam}{xfinal=true}
```

The second statement above reverses the toggle  $\langle xdraft \rangle$  to  $\langle false \rangle$ , which had been set in the first statement to  $\langle true \rangle$ .

Toggle keys may easily be confused with the conventional (native) boolean keys, especially at the time of key setting. It is, therefore, always safer to use the syntaxes in Subsection 8.2 for defining keys; they avoid interference between new and existing keys.

Note: If we were to use the key names draft and final as toggle keys above, instead of xdraft and xfinal, there would have been a clash with the keys draft and final defined as (complementary) native-boolean keys in Section 4— because they share the same family  $\langle fam \rangle$  and prefix  $\langle KV \rangle$ . The names draft and

final can be used as toggles only if the family  $\langle fam \rangle$  or prefix  $\langle KV \rangle$  is changed. See Subsection 8.2.1 for further details.

# 6.2 Unipolar toggle-boolean keys

The syntax for defining unipolar toggle keys is exactly the same as that for defining bipolar toggle keys:

```
Macro107\define@unitogkeys[\keyprefix\]]{\family\}[\macroprefix\]108{\primary toggle\}[\default value for primary toggle\]109{\secondary toggle\}{\func for primary toggle\}110{\func for secondary toggle\}.
```

Here too, if the user doesn't supply the  $\langle \text{keyprefix} \rangle$  and/or  $\langle \text{macroprefix} \rangle$ , the package will use  $\langle \text{KV} \rangle$  and  $\langle \text{mp@} \rangle$ , respectively. When the default value for the primary toggle key is not supplied, the package will use true.

```
        Example

        111
        \define@unitogkeys[KV]{fam}[mp@]{draft}[true]{final}%

        112
        {\def\x##1{}}{\def\y##1{##1}}

        113
        \setkeys[KV]{fam}{draft=true}% ''final'' becomes ''true'' here.
```

# 6.3 Biunipolar toggle-boolean keys

The interface for creating biuni toggle keys is exactly like that for creating other complementary boolean keys, except for the optional  $\star$  and + signs. The interface is as follows (the meaning of the optional  $\star$  and + is given in Subsection 4.3):

\_\_\_\_\_ <u>Macro</u> \_\_\_\_\_\_ \define@biunitogkeys\*+[{keyprefix}]{{family}}[{macroprefix}]

{\primary boolean}][\default value for primary boolean ]]

{secondary boolean}}{macro for primary boolean}}

```
114
115
116
117
```

 $\{\langle macro for secondary boolean \rangle\}$ 

```
Example
      \define@biunitogkeys+[KV]{fam}[mp@]{preprint}[true]{review}{%
118
        \iftog{mp@preprint}{%
119
          \def\banner{\fbox{\textsf{This is a preprint copy}}}%
120
        }{}%
121
      }{%
122
        \iftog{mp@review}{%
123
          \SKV@AtDocumentStart{\linespread{1.5}\selectfont}%
124
          \def\banner{\fbox{\textit{This is a review article}}}%
125
126
        }{%
          \let\banner\@empty
127
        }%
128
```

#### \setkeys[KV]{fam}{preprint=false or true}

# 7 Defining multiple keys of all genres by one command

The interface for defining multiple keys of all kinds in one go is the command \define@keylist, whose syntax is

131 132

	Macro	] —			
\define@keylist{\key type/id	), (key	$\langle k \epsilon \rangle$ , $\langle k \epsilon \rangle$	ey default	value>,	
<pre> key macro/function ; (anot</pre>	ther se	et of	key specif	iers $ angle$ ; e	etc}

There are five key types: 1 (ordinary key), 2 (command key), 3 (native-boolean key), 4 (toggle-boolean key), and 5 (choice/menu key). The key types can be indicated either in numeral format (1 to 5) or in alphabetic format (ord, cmd, bool, tog, choice, menu). "Choice" and "menu" key types imply the same thing (key type 5): the user can pick the name he prefers. The key and its attributes are separated by commas; they constitute one "object" or "instance". The objects are separated by the  $\langle keyparser \rangle$ , which is the semicolon in the above example.

If the key list is available in a macro, say,

\define@keylist\*\keylist.

Example

then the keys can be defined by the starred form of \define@keylist:

135

133

134

\define@keylist\* takes a macro as argument, while \define@keylist accepts a key list.

Example

The \define@keylist macro uses the following commands in the background:

```
Example136\define@key, \define@cmdkey, \define@boolkey,137\define@choicekey, \define@togkey.
```

Therefore, it assumes that it is safe to redefine a previously defined key. If this assumption is unwarranted, then the user should consider using the machinery of Subsection  $8.2.^*$ 

<sup>\*</sup>The machinery of Subsection 8.2 can be utilized to safely define new keys without the fear of inadvertently redefining an existing key within the same family and with the same key prefix.

### 7.1 Choice key values

The \choicekeyvalues macro is provided for defining choice keys; it lists the alternate admissible values for a choice key and thus can't be empty when a choice key is being defined via \define@keylist. Its syntax is

Macro

138

 $\label{eq:list} $$ \choicekeyvalues*[\langle prefix \rangle][\langle family \rangle]{\langle key \rangle}{\{\langle list \rangle\}}, $$$ 

where  $\langle list \rangle$  is a comma-separated list of admissible key values. Unless the key prefix or family changes, the unstarred variant of  $\langle choicekeyvalues$  wouldn't allow you to set two  $\langle choicekeyvalues$  for the same choice key. The starred variant  $\langle choicekeyvalues^{\star}$ , on the other hand, allows you to overwrite admissible choice values for a key within a specified family and with the given key prefix. The arguments  $\langle prefix \rangle$  and  $\langle family \rangle$  are optional, provided the key prefix and family have been specified before calling  $\langle choicekeyvalues$ , using  $\langle skvoptions$ . If  $\langle prefix \rangle$  and  $\langle family \rangle$  are not given, the prevailing key prefix and key family are used internally by  $\langle choicekeyvalues$  to build distinct alternate values list for the choice key. Therefore, any number of choice keys are allowed to appear in one  $\langle define@keylist or \langle define@keylist^{statement}$ , if their lists of alternate/admissible values have been set by  $\langle choicekeyvalues$ .

To further save tokens, the macro \choicekeyvalues may be abbreviated by \CKVS. It has to be provided for each choice key that is being defined.

For example, if we want to define two choice keys align and shootingmodes, then before the call to \define@keylist, we have to set

\CKVS{align}{center,right,left,justified}

Example \_\_\_\_

```
139
```

140

As mentioned earlier, the key family and other package options can be changed dynamically via

Example

\CKVS{shootingmodes}{portrait,indoor,foliage,underwater}

141 142 \skvoptions{keyparser=value,macroprefix=value,keyprefix=value, keyfamily=value}.

In line with the philosophy of the xkeyval package, all the choice keys to be defined using the skeyval package require a menu: choice keys, by definition, have pre-ordained or expected values.

#### 7.2 Some examples

In this section we provide a glimpse of the potential applications of the tools provided by the skeyval package in the context of defining multiple keys by one command.

Suppose that the key family and other attributes have been set as

144

Example

```
\skvoptions{keyparser=;,macroprefix=mp@,keyprefix=KV,
keyfamily=fam}
```

Further, suppose we wish to define a set of keys {color,angle,scale,align}. The key color will be defined as ordinary key, the keys angle and scale will de defined as command keys, while the key align will be defined as a choice key. Assume that the align key can only assume one of the values {center | right | left | justified}, where the first three values would further imply \centering, \flushright, and \flushleft, respectively. Moreover, we assume that the key scale will be associated with a macro called \mydo, which depends on a previously defined macro \do. Together with align, we would also like to define another choice key: weather. The key color isn't associated with any macro. Then we can do:

Example

```
% We use space freely in these examples for the sake
145
      % of illustration:
146
      \def\someweather{windy}
147
      \CKVS{align}{center,right,left,justified}
148
      \CKVS{weather}{sunny,cloudy,lightrain,heavyrain,snow,
149
        sleet,\someweather}
150
      \def\funcforalign{%
151
        \ifcase\nr\relax
152
          \def\mp@align{\centering}%
153
        \or\def\mp@align{\flushright}%
154
        \or\def\mp@align{\flushleft}%
155
        \or\let\mp@align\relax
156
        \fi
157
      }
158
      % Keys 'color' and 'mybool' have no macro.
159
      % Submitted value of key 'angle' is \#1 \rightarrow \mbox{mpCangle}.
160
      \define@keylist{%
161
        ord,color,gray!25,;
162
        cmd,angle,45,\def\anglevalue{##1};
163
        cmd,scale,1,\def\mydo####1{\do ####1};
164
        choice,align,center,\funcforalign;
165
        \listbreak;
166
        bool,mybool,true,;
167
        choice,weather,sunny,\edef\Weather{\val}%
168
      }
169
      \setkeys[KV]{fam}{angle=45,scale=1cm,weather=cloudy}
170
```

Note the number of parameter characters in the definition of  $\mydo$ . We will return to this matter in Subsection 7.2.1. The  $\nr$  and  $\alpha$ l macros are bin parameters for choice keys, as defined by the xkeyval package.  $\alpha$ l contains the user input for the current key and  $\nr$  contains the numeral corresponding to the numerical order of the user input in the  $\CKVS$  list, starting from 0 (zero).

For example, in the  $CKVS{align}$  list, the nr values are center (0), right (1), left (2), and justified (3). These parameters thus refresh with the choice key and its user-supplied value.

Instead of defining the macro \funcforalign before hand, we can submit its replacement text directly to the macro \define@keylist, but, because \funcforalign contains a conditional, some care is needed in doing so (see Subsection 7.5). Once the key align has been defined, the macro \funcforalign can't be reused before the key align is set. This is because it is at key setting time that the function \funcforalign would be called. This is uneconomical: it is thus desirable to submit the key macro directly to \define@keylist irrespective of the presence of conditionals.

Please note the **\listbreak** token inserted on macro line 166 above. Because of it, the keys mybool and weather will not be read and defined; all the keys before **\listbreak** (i.e., color, angle, scale and align) will be read and defined. All the entries for mybool and weather will instead be saved in the macro **\SKV@remainder**, possibly for some other uses.

Hundreds of keys can be defined efficiently in this way, using very few tokens. As another example, we consider the following keys:

```
\CKVS*{align}{center,right,left,justified}
171
      \CKVS{election}{state,federal,congress,senate}
172
      \def\funcfortextwidth{\AtBeginDocument{\wlog{'textwidth' %
173
        is '\mp@textwidth'}}
174
      \def\funcfortextheight{%
175
        \ifx\@empty\mp@textheight
176
          \wlog{'textheight' value empty}%
177
        \else
178
          \wlog{'textheight' value not empty}%
179
        \fi
180
      }
181
      \def\funcforpaperwidth{\wlog{'paperwidth' was defined as %
182
        ordinary key.}}
183
      \def\funcforalign{%
184
        \ifcase\nr\relax
185
          \def\mp@align{\centering}%
186
        \or\def\mp@align{\flushright}%
187
        \or\def\mp@align{\flushleft}%
188
        \or\let\mp@align\relax
189
        \fi
190
      }
191
        'boolvar', 'paperheight' and 'evensidemargin' have no
      %
192
      % key macros:
193
      \define@keylist{%
194
        bool,boolvar,true,;
195
```

```
ord,paperheight,\paperheight,;
196
197
        ord, paperwidth, \paperwidth, \funcforpaperwidth;
        cmd,textheight,\textheight,\funcfortextheight;
198
        cmd,textwidth,\textwidth,\funcfortextwidth;
199
        ord,evensidemargin,\evensidemargin;;
200
        tog,togvar,true,\iftog{mp@togvar}{\def\catch####1{####1}}%
201
          {\def\gobble####1{}};
202
        choice,align,center,\funcforalign;
203
        choice,election,congress,\def\electiontype{##1};
204
        cmd,testdim,2cm,\long\def\funcfortestdim###1{%
205
          A test dimension ####1 \endgraf\bigskip}%
206
      }
207
      \setkeys[KV]{fam}{togvar=true,testdim=1cm,election=senate}
208
```

The macro \electiontype corresponds to \val for choice key election. Again, the intermediate/utility key macros can be reused only after their associated keys have been set.

The same set of keys can be defined via the starred form of \define@keylist, as shown below:

```
Example
      \def\keylistvector{%
209
        bool,boolvar,true,;
210
        ord, paperheight, \paperheight,;
211
        ord, paperwidth, \paperwidth, \funcforpaperwidth;
212
        cmd,textheight,\textheight,\funcfortextheight;
213
        cmd,textwidth,\textwidth,\funcfortextwidth;
214
        ord, evensidemargin, \evensidemargin,;
215
        tog,togvar,true,\iftog{mp@togvar}{\def\catch####1{####1}}%
216
          {\def\gobble####1{}};
217
        choice,align,center,\funcforalign;
218
        choice,election,congress,\def\electiontype{##1};
219
        cmd,testdim,2cm,\long\def\funcfortestdim###1{%
220
          A test dimension ####1 \endgraf\bigskip}%
221
222
      \define@keylist*\keylistvector
223
```

Since the keys have been defined, they can now be set. In the following, we set only two of the keys:

Example

\setkeys[KV]{fam}{align=right,testdim=3cm}

224

The macro \mp@align holds the value \flushright, while \KV@fam@testdim holds the macros:

```
225 \def\mp@testdim{#1}
226 \long\def\funcfortestdim##1{A test dimension ##1},
```

where  $\langle \#1 \rangle$  is the value (3cm) submitted for the key testdim. The number of parameter characters normally increases in the macro \define@keylist (see Subsection 7.2.1). After setting the keys, you can do \show\mp@align and \show\KV@fam@testdim to confirm the above assertions.

Example

The rest of the defined keys can now be set as follows:

```
227
228
```

\setkeys[KV]{fam}{boolvar=true,paperheight,paperwidth, textheight,textwidth=6cm}

Try \show\ifmp@boolvar to confirm that boolvar is now (true); it was originally set as (false). The macro \KV@fam@paperwidth holds the function \funcforpaperwidth, while \mp@textheight holds the value submitted to key textheight at any instance of \setkeys. By the above \setkeys, only the default values of paperheight, paperwidth, and textheight are presently available.

Instead of using macros to pass key macros and functions, it is also possible to use token list registers. Some examples are provided below:

Example

```
\NewToks[temptoks]{a,b}
229
      \% See page 46 for definition of \NewToks and
230
      % related commands.
231
      \temptoksa{\ifmp@boola\def\do#1{%
232
        \def#1##1##2{\expandafter\expandafter\expandafter\in@
233
        \expandafter\expandafter\expandafter{\expandafter##1%
234
        \expandafter}\expandafter{##2}}\fi}
235
      \temptoksb{\iftog{mp@toga}{\def\order#1{Use '#1' now!}}%
236
        {\def\altorder#1{Don't use '#1' now!}}}
237
      \define@keylist{3,boola,true,\the\temptoksa;
238
        4,toga,true,\the\temptoksb}
239
      \setkeys[KV]{fam}{boola=true,toga=true}
240
```

The advantage of using token list registers is that the parameter characters need not be doubled in the token list registers, unlike when using macros. The token list register \temptoksa can be reused as soon as the key boola has been set. See Subsection 7.5.1 for more information on using macros and token list registers to parse key functions.

#### 7.2.1 Parameterized macros in key macros

The examples in Subsection 7.2 would have provided some glimpse of the rules guiding the use of parameter characters in key macros. The general rules are as follows:

- a) When key macros are parsed through token list registers, the parameter characters shouldn't be doubled.
- b) When key macros are parsed via intermediate macros, the parameter characters should be doubled but only once.
- c) In all other cases (i.e., when using \define@keylist and its starred variant) the parameter characters should be doubled twice.

 $T_EX$  will flag a fatal error when any of these rules is breached. The following examples illustrate the use of these rules. The commands \skif, \skifx, \skelse and \skfi are described in Subsection 7.5.2.

```
Example
      \define@keylist{%
241
        tog,toga,true,\iftog{mp@toga}{%
242
           \def\swear####1{Repeat after me: '####1'!}%
243
        }{%
244
           \let\swear\@gobble
245
        }%
246
      }
247
      \setkeys[KV]{fam}{toga=true}
248
      \NewToks[temptoks]{a}
249
      \temptoksa={\long\def\funcforproclaim#1%
250
        {A proclaimed statement: #1}}
251
      \define@keylist{%
252
        bool,boola,true,\skif{mp@boola}\def\yes###1%
253
           {Accept '####1'!}\skelse\def\no####1{Reject '####1'!}\skfi;
254
        cmd,proclaim,Statement,\the\temptoksa
255
      }
256
      \setkeys[KV]{fam}{boola=true,proclaim=nature}
257
      \CKVS{align}{left,right,center}
258
      \define@keylist{choice,align,center,
259
        \skifcase\nr
260
           \def\hold####1{\def####1#######1{===#######1===}}%
261
        \skor
262

# 7.3 The keycommand interface

The \define@keylist macro provides an interface for defining commands in the manner of the keycommand package. We haven't developed this interface well enough but the following example shows what is currently obtainable and the possibilities for future enhancements. It is hoped that further work in this direction will be undertaken in the future. I do foresee that the user interface will be made lighter in the future. For now, the \skvoptions command needs be reissued only when the key family changes, and in that case we simply have to do \skvoptions{keyfamily=name}. Any future enhancement should seek to hide the \setkeys command from the user.

	Example
335	keyparser=;,macroprefix=mp,keyprefix=KV,
336	keyfamily=rule}
337	<pre>\define@keylist{cmd,raise,.5ex,;cmd,width,1em,;</pre>
338	<pre>cmd,thick,.4pt,;bool,proclaim,true,}</pre>
339	\setkeys[KV]{rule}{raise,width,thick,proclaim=false}
340	\newcommand*\Rule[2][Hello]{%
341	\setkeys[KV]{rule}{#2}%

```
\rule[\mpraise]{\mpwidth}{\mpthick}%
342
343
        #1%
        \rule[\mpraise]{\mpwidth}{\mpthick}\hspace*{1em}%
344
        \ifmpproclaim \color{red}\fi\textdaggerdbl
345
      }
346
      \begin{document}
347
      \parindent\z@
348
      \begin{tabular*}\textwidth{rr}
349
      \verb+\Rule[width=2em]{hello}+:&
350
        \Rule[Hello World] {width=2em, proclaim} \cr
351
      \verb+\Rule[thick=1pt,width=2em]{hello}+:&
352
        \Rule{thick=2pt,width=2em}\cr
353
      \verb+\Rule{hello}+:&
354
        \Rule[Hello World] {proclaim} \cr
355
      \verb+\Rule[thick=1pt,raise=1ex]{hello}+:&
356
        \Rule[Hello World]{thick=1pt,raise=1ex}
357
      \end{tabular*}
358
      \end{document}
359
```

# 7.4 Input error

Native-boolean, toggle-boolean and choice keys issue error messages if the key value is not valid, i.e., not in the list of admissible values. The admissible values of native-boolean and toggle keys are true and false. The valid values of choice keys are set by the user via \CKVS. The default input error is defined by the macro \SKV@inputerr. It takes two arguments (i.e., value and key) and can be customized by the user.

# 7.5 Conditionals in key macros

The  $T_EX$  conditional primitives if, ifx, else and fi cannot appear in the key macro when define@keylist is being invoked. The reason can be traced to the discussion on page 211 of the  $T_EXBook$  and the loops used in the skeyval package to define keys by means of define@keylist. There are many possible approaches to resolving this problem, but only four appear to be attractive (see Subsections 7.5.1 to 7.5.4).

7.5.1 Burying conditionals in intermediate macros or token list registers

Key macros/functions involving conditional operations such as

```
    Example

    \ifmp@bool \do \else \donot \fi
```

can be submitted to define@keylist via intermediate macros, as seen above (in Subsection 7.2), but the approach isn't economical and thus not advisable. Nevertheless, we give more examples of deploying intermediate macros below. Let the key macro prefix be mp@, the key prefix be KV, and the key family be fam.

Suppose we want to submit the following:

```
361 \define@keylist{3,bool,true,\ifmp@bool \do \else \donot \fi}.
```

The presence of if and fi in the argument will trigger an error when  $T_EX$  is scanning and skipping tokens, and, secondly, because of the loops and conditionals used by the skeyval package in defining keys via define@keylist. Neither protect nor noexpand is helpful here. One solution is to first define

```
362
```

363

and then do

```
    Example

    \define@keylist{3,bool,true,\funcforbool},
```

which will execute functorbool when the key bool is set. One significant drawback of this approach is that once the key bool has been defined by the above statement, the function functorbool may not be redefined and reused before the key bool is set. This is wasteful and not advisable. This approach is included here only for demonstration purposes. The schemes in Subsections 7.5.2 to 7.5.3 are preferable.

As another example, we may do

```
Example364\def\funcforboola{\ifmp@boola\def\do##1{%365\def##1####1####2{\expandafter\expandafter\expandafter\expandafter\expandafter366\expandafter\expandafter\expandafter{expandafter{expandafter}\expandafter}\expandafter{*###2}}\fi}367\expandafter}\expandafter{####2}}\fi}368\define@keylist{3,boola,true,\funcforboola}369\setkeys[KV]{fam}{boola=true}370\def\y{x} \def\z{xxx} \do\x \x\y\z
```

Token list registers can be used here economically instead of macros. Below we define one native-boolean key and one toggle-boolean key:

```
      Barrow Example

      371
      \NewToks[temptoks]{a,b}

      372
      \temptoksa{\ifmp@boola\def\do#1{%

      373
      \def#1##1##2{\expandafter\expandafter\expandafter\in@

      374
      \expandafter\expandafter\expandafter{\expandafter##1%

      375
      \expandafter}\expandafter{##2}}\fi}

      376
      \temptoksb{\iftog{mp@toga}{\def\order#1{Use '#1' now!}}}
```

379

```
\define@keylist{3,boola,true,\the\temptoksa;
   4,toga,true,\the\temptoksb}
```

\setkeys[KV]{fam}{boola=true,toga=true}

You can see the significant reduction in the number of parameter characters when using token list registers. The utility token list registers \temptoksa and \temptoksb can be reused to define many other keys as soon as the keys boola and toga have been set. However, as noted earlier, the approach of using intermediate macros and token list registers to parse arguments to \define@keylist is not attractive because of the overheads in the number of macros and token list registers.

#### 7.5.2 Using pseudo-primitives to submit the conditionals

There are two downsides to the above approach of hiding conditionals in macros: the macros have to be defined and, although they can be redefined and reused (after the associated key has been set), they tend to defeat the initial aim of the package, which is to economize on tokens.

Suppose we want to define a native-boolean key mybool with the following key macro:

```
Example

380 \ifmp@mybool

381 \def\hold##1{\def##1####1{***###1***}}%

382 \else

383 \def\hold##1{\def##1####1{===}}%

384 \fi
```

where the key prefix KV, key family fam, and the macro prefix mp@ are assumed to have been defined previously. Then, instead of hiding the conditional in an intermediate macro, we may adopt the following:

```
Example

385 \define@keylist{3,mybool,true,

386 \skif{mp@mybool}\def\hold##1{\def##1####1{***####1***}}%

387 \skelse\def\hold##1{\def##1####1{===####1===}}\skfi

388 }

389 \setkeys[KV]{fam}{mybool=true or false}

390 \hold\x
```

Here we have used <code>\skif{mp@mybool}</code>, <code>\skifx</code>, <code>\skelse</code> and <code>\skfi</code> for the commands <code>\ifmp@mybool</code>, <code>\ifx</code>, <code>\else</code> and <code>\fi</code>, respectively, to hide the latter four from T<sub>E</sub>X's scanning and skipping mechanism. It should be noted that <code>\skif{mp@mybool}</code> requires that the argument <code>(mp@mybool)</code> be enclosed in braces. Something like <code>\skifmp@mybool</code> will be interpreted by T<sub>E</sub>X as an undefined control sequence when the key <code>mybool</code> is being set. Defining the command

\skif{mp@mybool} to be \ifmp@mybool before hand would have failed because T<sub>F</sub>X's scanner would then get the hint of the assignment.

Note: We haven't found any package that has defined \skif, \skifx, \skelse, \skfi, \skifcase or \skor. The xifthen package uses \OR, not \skor. If the situation changes in the future (i.e., if a package is observed to have defined any of these commands), they will be appropriately modified in the skeyval package. Information and feedback from package users is solicited in this regard.

We have redefined the \setkeys command of the xkeyval package to recognize that \skif{boolean}, \skifx, \skelse, \skfi, \skifcase and \skor stand for \ifboolean, \ifx, \else, \fi, \ifcase and \or, respectively. The redefined \setkeys command has the same syntax as as in xkeyval package:

```
391
392
393
```

Macro 

394

No errors are produced if any of the sets (prefix), (families), (na), and  $\langle keys=values \rangle$  is empty. In fact, an instruction such as  $stkeys[]{}[]{}$ is completely benign, and so is \setkeys{}{}.

**Conditionals involving** \ifcase: The case of conditionals involving \ifcase can be handled in the same way as those involving \if:

```
Example
      \CKVS{focus}{center,left,right,justified}
395
      \temptoksa{\ifcase\nr\relax
396
        \def\mp@focus{\centering}\or\def\mp@focus{\flushright}
397
        \or\def\mp@focus{\flushleft}\or\let\mp@focus\relax\fi}
398
      \define@keylist{5,focus,center,\the\temptoksa}
399
```

This can be written more compactly as follows, which obviates the need for intermediate macros and list registers:

Example

```
\define@keylist{menu,focus,center,\skifcase\nr\relax
400
        \def\mp@focus{\centering}\skor\def\mp@focus{\flushright}
401
        \skor\def\mp@focus{\flushleft}\skor\let\mp@focus\relax\skfi}
402
```

Here, the skeyval package uses \skifcase, \skor, and \skfi for \ifcase, \or and fi, respectively; otherwise,  $T_{FX}$  would be grumpy.

The key focus can now be readily set: \setkeys[KV]{fam}{focus=left}.

7.5.3 Using switches to submit the conditionals

The approaches of Subsection 7.5.2 provide a familiar  $T_EX$ -like syntax for submitting conditionals to \define@keylist. There is yet another approach that we developed. It is related to the native  $T_EX$  boolean conditional. By *switches* we mean the usual  $T_EX$ 's \iftrue and \iffalse booleans, but expressed in a different semantics.

A new switch can be introduced by using the following command:

 Macro

 \newswitch{{switch}}{{value/state}}

There should be no \if in (switch) when using \newswitch. Valid values/states of switches are 'true' (or 'on') and 'false' (or 'off'). With this definition you can issue \if(switch), \(switch)true, and \(switch)false. One advantage of \newswitch is that a switch can start off as either true (or on) or false (or off), unlike the classical T<sub>E</sub>X's case in which all booleans start off as false. Also, switches can be used where primitive T<sub>E</sub>X conditionals may prove impossible. For example, we know that you can't do \let\ifabc\iftrue within the body of a conditional text without hiding the assignment from T<sub>E</sub>X's scanning mechanism.

You can define many switches in a row by the following command:

404

403

Each member of  $\langle switches \rangle$  is prefixed with  $\langle prefix \rangle$  upon definition. The optional  $\langle state \rangle$  can be either true or false.

Macro

Here are some examples:

Example

```
405\[\] NewSwitches{x,y,z}\]406\rightarrow \newswitch{x}{false} \newswitch{y}{false}407\[\] newswitch{z}{false}\]408\[\] NewSwitches[skv@]{u,w}[true]\]409\rightarrow \newswitch{skv@u}{true} \newswitch{skv@u}{true} \newswitch{skv@u}{true}\]
```

Switches may be set and tested using the following commands:

		Г	Macro
410	$\setswitch{\langle switch \rangle}{\langle value \rangle}$	alue/st	
411	$\operatorname{switchon}{\operatorname{switch}}$	$\rightarrow$	$\langle witch \rangle$ true
412	$switchtrue{switch}$	$\rightarrow$	$\langle witch \rangle$ true
413	$\operatorname{switchoff}(\operatorname{switch})$	$\rightarrow$	$\langle witch \rangle$ false

```
switchfalse{switch}
                                               \langle \text{switch} \rangle false
414
                                       \rightarrow
415
       ifswitchon{\langle switch \rangle}{\langle true text \rangle}{\langle false text \rangle}
       ifswitchtrue{\langle switch \rangle}{\langle true text \rangle}{\langle false text \rangle}
416
       ifswitchoff{(switch)}{(not true)}{(not false)}
417
       \tilde{\phi} = {\langle switch \rangle} {\langle not true \rangle} {\langle not false \rangle}
418
                                             Example
       NewSwitches{w,x,y,z}
419
       \setswitch{w}{true}
                                            420
       setswitch{x}{on}
                                            421
                                     \rightarrow
       \setswitch{y}{false}
                                    \rightarrow
                                            \setswitch{y}{off}
422
       setswitch{z}{off}
                                            \setswitch{z}{false}
423
       ifswitchon{x}{\det}xx{0n}}{\det}xx{0ff}}
424
       \ifswitchoff{y}{\def\yy{Off}}{\def\yy{On}}
425
```

Suppose the key prefix is KV, the key family is fam, and the key macro is mp@. The the following works:

```
      426
      \define@keylist{3,switcha,true,

      427
      \ifswitchon{mp@switcha}{\def\say{Swtich 'a' is true}}

      428
      {\def\say{Swtich 'a' is false}}}

      429
      \setkeys[KV]{fam}{switcha=true or false}
```

Note: Please note that switch keys are boolean keys (type '3' key). As yet, when setting switch keys you must supply either true or false, not on or off.

#### 7.5.4 Using toggles to submit the conditionals

Toggle booleans, described in Section 5, can also be used to circumvent the problem of matching if and fi in difficult circumstances, since toggles aren't T<sub>E</sub>X primitives, and, as noted in Section 5, toggles are very economical. For example, the following works:

```
Example430\define@keylist{4,toga,true,431\iftog{mp@toga}{\def\say{Toggle 'a' is true}}%432{\def\say{Toggle 'a' is false}}}433\setkeys[KV]{fam}{toga= true or false}
```

where the key prefix, key family, and macro prefix are still assumed to be KV, fam, mp@, respectively. Recall that toggle keys are type '4' keys.

#### 8 CHECKING AND REDEFINING KEYS

#### 8.1 Checking the status of a key

Three mechanisms have been introduced in the skeyval package to ascertain the statuses of keys. These are as follows.

434

	Macro	<u> </u>
$\label{eq:linear} \label{eq:linear} $$ \eqrefined[\prefixes\] {\family} \label{eq:linear} eq:$	$\mathtt{amilies} angle$	$\{\langle key \rangle\} \{\langle true \rangle\} \{\langle false \rangle\}$

This executes  $\langle true \rangle$  if  $\langle key \rangle$  is defined, reserved, or suspended with a prefix in (prefixes) and family in (families); it returns (false) otherwise. This is similar to the xkeyval package's \key@ifundefined, but, apart from reversing the logic of the test, \ifkeydefined loops over prefixes (in addition to looping over families) to locate the key, and also considers reserved and suspended keys as defined. The lists (prefixes) and (families) may contain nil, one or more elements.

Macro

435

 $ifkeyreserved[\langle prefixes \rangle] {\langle families \rangle} {\langle key \rangle} {\langle true \rangle} {\langle false \rangle}$ 

This returns  $\langle true \rangle$  if  $\langle key \rangle$  is reserved with a prefix in  $\langle prefixes \rangle$  and family in (families); it returns (false) otherwise. Reserved keys are introduced in Subsection 9.3.

Macro  $ifkeysuspended[\langle prefixes \rangle] {\langle families \rangle} {\langle key \rangle} {\langle true \rangle} {\langle false \rangle}$ 

436

This executes  $\langle true \rangle$  if  $\langle key \rangle$  is suspended with a prefix in  $\langle prefixes \rangle$  and family in (families); it executes (false) otherwise. Suspended keys are introduced in Subsection 9.4.

### 8.2 Unintentional redefinition of keys

The xkeyval package, by default, permits the automatic redefining of keys of the same (prefix) and (family): at the point of defining a new key, the package doesn't, by default, check whether or not the key had been previously defined with the same  $\langle prefix \rangle$  and  $\langle family \rangle$ . In some circumstances this can be undesirable, and even dangerous, especially if the same key (of the same (prefix) and (family) is mistakenly redefined with different macros/functions in the same package or across packages. One way to solve this problem is to use xkeyval package's \key@ifundefined command (or the skeyval package's \ifkeydefined) to confirm the status of a key prior to its definition. However, using these commands before defining every key can be laborious.

Consider the following two scenarios:

 Example

 437
 \define@key[KV]{fam}{keya}[\$\star\$]{\def\tempa##1{##1}}

 438
 \define@boolkey[KV]{fam}{keya}[true]{%

 439
 \ifKV@fam@keya\def\tempb{#1}\fi}

 440
 \setkeys[KV]{fam}{keya=\$\textbullet\$}

Obviously the two definitions of  $\langle \text{keya} \rangle$  are valid and will be implemented but the  $\langle \text{setkeys} \rangle$  command here will issue an unintelligible error message, like LATEX's "You are in trouble here ...". The key  $\langle \text{keya} \rangle$  has been defined twice and  $\langle \text{setkeys} \rangle$  has sought to use its latest definition to set its value, which is incorrect. As mentioned in Subsection 5.2, the  $\langle \text{setkeys} \rangle$  command (and friends) of the xkeyval package doesn't know if a key has been redefined in the same  $\langle \text{family} \rangle$  and with the same  $\langle \text{prefix} \rangle$ . At the high level, it doesn't consider the key type: it uses the latest definition of the key to set its value using the key's macro. This is particularly worrisome in the case of toggle keys, since although toggle keys have their own separate namespace, they can easily be confusing (at least to  $\langle \text{setkeys} \rangle$  if they have names identical to other keys within the same family and with the same prefix. In fact, the problem can manifest itself in more ways than the scenario just depicted.

If the package option verbose is enabled, the skeyval package provides a warning system (by making an entry in the transcript log file) if an existing key is being redefined (within the same family and with the same prefix) by any of the following commands:

	Macro
441	\define@key, \define@cmdkey, \define@cmdkeys,
442	\define@choicekey, \define@boolkey, \define@boolkeys,
443	\define@biboolkeys, \define@uniboolkeys, \define@biuniboolkeys,
444	\define@togkey, \define@togkeys, \define@bitogkeys,
445	\define@unitogkeys, \define@biunitogkeys

The machinery of Subsection 8.2.1 can be used to avoid inadvertently redefining existing keys.

#### 8.2.1 Avoiding multiple definitions of same key

For the above reasons, the skeyval package introduces the following commands, which have the same syntaxes as their counterparts from the xkeyval and skeyval packages but which bar the user from repeated definition of keys with identical names within the same  $\langle \texttt{family} \rangle$  and with the same  $\langle \texttt{prefix} \rangle$ :

```
Macro446% The following defines ''ordinary'' keys (the counterpart<br/>% of \define@key from the xkeyval package):<br/>\newordkey[<prefix>]{<family>}{<key>}[<default>]{<funtion>}449% Counterpart of \define@cmdkey:
```

```
\mbox{newcmdkey}[\langle prefix \rangle] {\langle family \rangle}[\langle mp \rangle] {\langle key \rangle}[\langle default \rangle] %
450
                           \{(\texttt{funtion})\}
451
                    % Counterpart of \define@cmdkeys:
452
                    \mbox{newcmdkeys}[\langle prefix \rangle] \{\langle family \rangle\} [\langle mp \rangle] \{\langle keys \rangle\} [\langle default \rangle]
453
                    % Counterparts of \define@boolkey:
454
                    455
                           \{(\texttt{funtion})\}
456
                    \timestyle \label{eq:loss} $$ \timestyle \
457
                           {(funtion1)}{(funtion2)}
458
                    % Counterpart of \define@boolkeys:
459
                    \label{eq:loss} \label{eq:lo
460
                    % Counterpart of \define@biboolkeys:
461
                     462
                           {\primary boolean}][\default value for primary boolean ]]
463
                           {secondary boolean}}{<func for primary boolean}}</pre>
464
                           \{ \langle \text{func for secondary boolean} \rangle \}
465
                    % Counterpart of \define@uniboolkeys:
466
                    \mbox{newuniboolkeys}[\langle prefix \rangle] {\langle family \rangle}[\langle mp \rangle]
467
                           {\primary boolean}][\default value for primary boolean ]]
468
                           {secondary boolean}}{<func for primary boolean}}</pre>
469
                           {\dim \text{for secondary boolean}}
470
                    % Counterpart of \define@biuniboolkeys:
471
                    472
                           {\primary boolean}][\default value for primary boolean ]]
473
                           {secondary boolean}}{func for primary boolean}}
474
                           \{ \langle func for secondary boolean \rangle \}
475
                    % Counterparts of \define@togkey:
476
                     477
                           \{(\texttt{funtion})\}
478
                    479
                           \{(\texttt{funtion1})\}\{(\texttt{funtion2})\}
480
                    % Counterpart of \define@togkeys:
481
                    \mbox{newtogkeys[(prefix)]{(family)}[(mp)]{(keys)}[(default)]}
482
                    % Counterpart of \define@bitogkeys:
483
                    \mbox{newbitogkeys}[\langle prefix \rangle] {\langle family \rangle}[\langle mp \rangle]
484
                           {\primary toggle}}[\default value for primary toggle}]
485
                           {secondary toggle>}{{func for primary toggle>}
486
                           \{ \langle func for secondary toggle \rangle \}
487
                    % Counterpart of \define@unitogkeys:
488
                    \mbox{newunitogkeys}[\langle prefix \rangle] {\langle family \rangle}[\langle mp \rangle]
489
```

```
{\primary toggle}}[\default value for primary toggle}]
490
        {secondary toggle}}{func for primary toggle}}
491
        \{ \langle func for secondary toggle \rangle \}
492
      % Counterpart of \define@biunitogkeys:
493
      \mbox{newbiunitogkeys}[\langle prefix \rangle] \{\langle family \rangle\}[\langle mp \rangle]
494
        {\primary toggle}}[\default value for primary toggle \]
495
        {secondary toggle>}{{func for primary toggle>}
496
        \{ \langle func for secondary toggle \rangle \}
497
      % Counterparts of \define@choicekey:

      \newchoicekey[{prefix}]{{family}}{key}[{bin}]{alt}%
499
        [\langle default \rangle] \{\langle funtion \rangle\}
500
      501
        [\langle default \rangle] \{\langle funtion \rangle\}
502
      503
        [\langle default \rangle] \{\langle funtion1 \rangle\} \{\langle funtion2 \rangle\}
504
      505
        [\langle default \rangle] \{\langle funtion1 \rangle\} \{\langle funtion2 \rangle\}
506
      % Counterpart of \define@keylist:
507
      508
        (key macro/function); (another set of key specifiers); etc}.
509
```

The following aliases are defined in the skeyval package:

			Macro
510	\define@menukey*+	$\rightarrow$	\define@choicekey*+
511	\newmenukey*+	$\rightarrow$	\newchoicekey*+

We could simply have redefined/modified the legacy key definition commands in the xkeyval package to make it impossible to define keys of the same name in the same family and with the same prefix, but this approach would be unsafe since there are many packages using the xkeyval package and those packages may well have redefined identical keys. Moreover, the legacy key definition commands from the xkeyval package may be needed to redefine a disabled key (see Section 9).

All the commands of the type \newxxkey\* are robust and may be used in expansion contexts without fear of premature expansion, although expandable tokens in the definition may need to be protected.

With the above macros, the following will flag an understandable error message, namely that the key  $\langle keya \rangle$  is about being redefined in the same family  $\langle fam \rangle$  and with the same prefix  $\langle KV \rangle$ :

<sup>\*</sup>We shall refer to keys of the type  $\newxxxkey$  as those of category  $\newkey$ , and keys of the type  $\define@xxxkey$  as those of category  $\definekey$ .

	Example
510	\newordkey[KV]{fam}{keya}[\$\star\$]{\def\tempa##1{##1}}
512	(newordkey[kv][ram][keya][@(scar@][(der(cemba##r[##r]]
513	\newboolkey[KV]{fam}{keya}[true]{%
514	\ifKV@fam@keya\def\tempb{#1}\fi}

# 9 DISABLING, LOCALIZING, RESERVING, SUSPENDING, RESTORING, AND REMOVING KEYS

Besides macros for defining keys, the skeyval package also introduces mechanisms for disabling, localizing, reserving, suspending, restoring, and completely removing existing keys.

#### 9.1 Disabling keys

The skeyval package has modified the definition of \disable@keys from the xkeyval package to allow for looping over key prefixes and key families and for bespoke warnings and error messages, without engendering any potential conflict with the legacy \disable@keys. The new command is still called \disable@keys and has the same syntax as the native \disable@keys of the xkeyval package, except that the new command accepts key prefixes (instead of just one prefix) and key families (instead of just one family):

Macro

515

 $\label{eq:linear} \label{eq:linear} \label{eq:linear} \$ 

Here  $\langle prefixes \rangle$ ,  $\langle families \rangle$ ,  $\langle keys \rangle$  are lists of comma-separated entries referring to the keys to be disabled. Each of the lists  $\langle prefixes \rangle$ ,  $\langle families \rangle$ ,  $\langle keys \rangle$  may contain nil, one or more elements. If any of the members in  $\langle keys \rangle$  can't be located in  $\langle families \rangle$  and with prefix in  $\langle prefixes \rangle$ , an informational (not error) message is logged in respect of this member, but only if the package option verbose is selected.

The legacy version of \disable@keys (i.e., that of the xkeyval package) is still available via the starred variant:

516

 $disable@keys*[\langle prefix \rangle]{\langle family \rangle}{\langle keys \rangle}$ 

Note that this doesn't accept key prefixes and families, but only one key prefix and only one key family: the \disable@keys command from the xkeyval package can only be used to disable keys with the same  $\langle prefix \rangle$  and from the same  $\langle family \rangle$ , but not across prefixes and families.

Any attempt to subsequently set or use a disabled key will prompt the following error message. (The xkeyval package issues a warning in this case.) The error message can be modified by the user, but the names of the controls \SKV@disabledkey@err and \SKV@disabledkey should be retained.

```
Macro
        \def\SKV@disabledkey@err{%
517
           \PackageError{skevval}{%
518
             Key \langle \text{key} \rangle with prefix \langle \text{prefix} \rangle in family \langle \text{family} \rangle
519
             was disabled on input line (lineno)
520
          ን የ
521
             You can't set or reset \langle \text{key} \rangle at this
522
             late stage. Perhaps you're required to set it
523
             earlier, within a package or in the document's preamble.
524
          }%
525
        }
526
```

If the user attempts to disable an undefined key, the xkeyval package issues a fatal error; the skeyval package, on the other hand, issues a warning in the transcript log file (if the package option verbose is selected), since the situation isn't fatal to the outcome of the LATEX pass or the document.

Disabled keys can be redefined with commands in the \definekey category but not with commands in the \newkey category, since a disabled key remains defined: only its macro has been replaced by an error message signifying the disabling of the key.

**Note:** Reserved and suspended keys can't be disabled, until they are unreserved or restored (see Subsections 9.3 to 9.4).

## 9.2 Localizing keys

By localizing a key we mean disabling a key at the end of the current class or package file. This is basically the command \disable@keys executed on the hook \SKV@BeforeClassEnd or \SKV@BeforePackageEnd, depending on \@currext. The hooks \SKV@BeforeClassEnd and \SKV@BeforePackageEnd are described in Section 13 (macro lines 836 to 837).

Macro

The syntax for localizing keys is exactly like that for disabling keys:

 $\label{eq:localize} \label{eq:localize} \lab$ 

If any of the members of the set  $\langle keys \rangle$  is not found in any of the members of  $\langle families \rangle$  and with a prefix from  $\langle prefixes \rangle$ , an informational message is written into the log file (if the package option verbose is selected), but no errors are flagged.

The starred variant of \localize@keys disables the keys listed in  $\langle keys \rangle$ , not at the end of the package or class file, but right before the start of document (i.e., at the boundary between the document preamble and \AtBeginDocument):

Macro

528

527

 $localize@keys [\langle prefixes \rangle] {\langle families \rangle} {\langle keys \rangle}.$ 

The hook used here is \SKV@BeforeDocumentStart, described in Section 13, macro line 841.

A key can be localized as soon as it is defined. In fact, a key can be localized even before it is defined: the actual disablement of the key will take place at the execution of the contents of \SKV@BeforeClassEnd or \SKV@BeforePackageEnd or \SKV@BeforeDocumentStart.

Localized keys can be redefined with commands in the \definekey category, but not with commands in the \newkey category.

## 9.3 Reserving and unreserving keys

The xkeyval package bars its users from defining new keys with XKV as a prefix. The skeyval package generalizes this concept via the following three developer macros:

Macro

529

 $ReserveKeyPrefixNames{(list)}$ 

This allows the package developer to bar the future use of names appearing in  $\langle list \rangle$  as key prefixes when defining, disabling, reserving and suspending keys; but not when setting keys. The  $\langle list \rangle$ , whose members are comma-separated, can be populated by the package developer as required.

530

531

Macro

This has a similar functionality to \ReserveKeyPrefixNames, but applies to macro prefixes instead of key prefixes.

Macro

This reserves family names  $\langle list \rangle$  and prevents further use of members of  $\langle list \rangle$ .

**Note:** The lists in these macros are scanned only when defining, disabling, reserving or suspending keys, and not when setting existing keys. If the lists were also to be scanned when keys are being set, then a situation could arise in which existing keys (including those defined by prior packages) couldn't be set.

These macros could be used, for instances, to secure against future use the key prefixes, macro prefixes, and key families that have used in a new style or class file. For example, we have used these facilities to bar users of the skeyval package from using the key prefix SKV, the family name skeyval, and the macro prefix SKV@ to define new keys in their packages.

	Macro
532	$\ \$
533	$\ReserveMacroPrefixNames \{ (list) \}$
534	\ReserveKeyPrefixNames*{{list}} \ReserveMacroPrefixNames*{{list}} \ReserveFamilyNames*{{list}}

These starred variants take effect at end of current package; the unstarred ones above assume immediate effect. If the developer wants to use any member of  $\langle list \rangle$  in his own package, it may be necessary for him to use the starred versions.

In addition to the above reservation commands, the skeyval package also introduces the following command:

Macro

535

where the lists  $\langle \text{prefixes} \rangle$ ,  $\langle \text{families} \rangle$ ,  $\langle \text{keys} \rangle$  can contain nil, one or more elements. Defined, reserved and suspended keys can't be reserved.

Reserved keys have to be unreserved with the following command before they can be defined and used:

536

	Macro	
$\mbox{unreserve@keys[{prefixes}]}$	{{familie	$\left \left\langle keys \right\rangle \right\}$

where, again, the lists  $\langle \text{prefixes} \rangle$ ,  $\langle \text{families} \rangle$ ,  $\langle \text{keys} \rangle$  can contain nil, one or more elements. If a key was not previously reserved, this command will simply issue an informational message in the log file (if the package option verbose is selected) and ignore that key. Defined keys and suspended keys can also be unreserved, which is equivalent to removing the keys (see Subsection 9.5).

# 9.4 Suspending and restoring keys

For some keys, it might be preferable to temporarily suspend them from a family (rather than disable or remove them) and restore them later. In this way, a key's state and macro can be frozen while the key remains defined.

Macro

The syntax for suspending keys is

537

 $\suspend@keys[\langle prefixes \rangle]{\langle families \rangle}{\langle keys \rangle},$ 

where the lists  $\langle prefixes \rangle$ ,  $\langle families \rangle$ ,  $\langle keys \rangle$  can contain nil, one or more elements. A key of particular prefix not previously defined in a family can't be suspended from that family. Similarly, a key previously suspended from a family can't be suspended again (for the second time) from the same family without being first restored in that family.

Suspended keys can be restored to their frozen states (*ex ante* suspension) by the following command:

Macro

538

Only keys (with a given prefix) previously suspended from a family can be restored in that family: "unsuspended" keys can't be restored.

# 9.5 Removing keys

The skeyval package provides for removing keys completely, such that any attempt to set or use a removed key will prompt the error message that the key is undefined in the given family and with the given prefix. The command \key@ifundefined from the xkeyval package and the macro \ifkeydefined from the skeyval package will both identify a removed key as undefined. The syntax for removing keys is:

Macro

539

 $\mbox{remove@keys[(prefixes)]{(families)}}{(keys)}$ 

Removed keys can't be restored but can be redefined with the commands in both the \newkey and \definekey categories.

## 10 User-value keys

We define these keys as those for which the user must supply values at key setting time whether or not the keys have default values. All the commands for defining new keys have a facility for providing the default value of a key, which would be used by the \setkeys macro if the user didn't supply a value for the key. If no default value has been specified for a key at definition time and no value is provided at key setting time, the xkeyval package will issue a fatal error. This scenario is preserved by the skeyval package. In addition, the skeyval package introduces a facility for requiring a user to supply a value for a key whether or not that key had a default value at definition time. Why is this necessary or useful? You may specify default values for keys in a package or class file to aid future revisions of the package, or for other purposes, but such values may not be suitable for all users—or indeed for any user. Examples of this type of situation abound: the signatory to a letter, the module code or title in a faculty programme, etc.

The following command can be used to require a user to supply a value for a key at key setting time, whether or not that key has a default value:

540

where  $\langle keys \rangle$  is the list of keys with  $\langle prefix \rangle$  and in  $\langle family \rangle$  for which the user must supply values at key setting time. It is obviously not logical to loop over key prefixes or families in this case. What the command  $\langle uservaluekeys$  does is to populate the container  $\langle KVQ \rangle prefix \rangle Q \langle family \rangle Q uservalue which is scanned for user-value key names at key setting time.$ 

The **\uservaluekeys** macro works incrementally, i.e., new inputs are added to an existing list for the family in question only if they haven't previously been included.

Example

541 542

\newboolkey[KV]{fam}[mp@]{boola}[true]%

 $\mbox{wcmdkey[KV]{fam}[mp0]{keya}[12pt]{\defx{#1}}$ 

```
543 {\ifmp@boola\def\x{#1}\fi}
544 \uservaluekeys[KV]{fam}{keya,boola}
545 \setkeys[KV]{fam}{keya,boola=true}
546 → Error (no value supplied for 'keya')
```

# 10.1 Using pointers to dynamically indicate user-value keys

Instead of using the macro \uservaluekeys to accumulate user-value keys, there is another way to dynamically specify these keys at key definition time: by using pointers. At key definition time, the pointers \uservalue and \guservalue can be associated with a user-value key. In the following statements, the pointer \uservalue specifies that the user of the affected key must supply a value at the time of using/setting the key. The pointer \uservalue has local effect, i.e., its impact can't escape local groups; on the other hand, \guservalue has global effect, i.e., using it within or out of a local group means that the user of the affected key must specify a value for the key at key setting time. \guservalue ensures that the internal container \SKV@(prefix)@(family)@uservalue is defined globally so that the settings can escape local groups.

```
      Example

      547
      \newordkey[KV]{fam}{\uservalue{keya}}[12pt]{\def\x{#1}}

      548
      \define@togkey+[KV]{fam}[mp@]{\guservalue{toga}}[true]%

      549
      {%

      550
      \iftog{mp@toga}{\def\x{#1}}{}%

      551
      }{%

      552
      \@latex@error{Value '#1' not valid}\@ehc

      553
      }
```

As these examples show, the newly introduced pointers (namely, \uservalue and \guservalue) can be used to dynamically build a list of user-value keys. See Section 11 for more comments on pointer systems.

# 11 EXTENSIONS TO THE POINTER SYSTEM OF THE **XKEYVAL** PACKAGE

The xkeyval package introduced a key pointer system. This basically involves the pointers \savevalue, \gsavevalue, and \usevalue. However, by the mechanism of that package, these pointers could be used only within the \setkeys command or context. In the key definition commands, the \usevalue pointer could also be used in default values of keys, as in

	Example
554	\define@key{fam}{keya}{\def\keya{#1}}
555	\define@key{fam}{keyb}[\usevalue{keya}]{\def\keyb{#1}}
556	\define@key{fam}{keyc}[\usevalue{keyb}]{\def\keyc{#1}}

```
557 \setkeys{fam}{\savevalue{keya}=test}
558 \setkeys{fam}{\savevalue{keyb}}% Yes, this also works.
559 \setkeys{fam}{keyc}
```

The default values of keys are called (invoked) within \setkeys. The pointers can't, however, be used as part of key names outside default values. The following, e.g., fails:

Example

560

# \define@key{fam}{\savevalue{keya}}{\def\keya{#1}}

The skeyval package has extended the pointer system to be issuable as part of key names within key definition commands in the two scenarios illustrated above (within and outside default values). Moreover, the pointers \savevalue and \gsavevalue can be deployed concurrently with \uservalue and \guservalue of Subsection 10.1 within the same key definition command. In combining the two pointer subclasses (i.e., \savevalue subclass and \uservalue subclass) in the same key definition command, it doesn't matter which subclass comes first, as the following examples show.

The pointers savevalue and gsavevalue make entries into the container  $XKV@\langle prefix \rangle@\langle family \rangle@save$  that is used by the xkeyval package to hold keys whose values should be saved at key setting time. The difference between savevalue and gsavevalue is that the former has a local effect while the latter can escape local groups (similar to the group properties of savevalue and gsavevalue of Subsection 10.1). The pointers savevalue and gsavevalue of the skeyval package are entirely compatible with those of the xkeyval package. One additional new feature is that the pointer gsavevalue prompts the global revision of the container  $XKV@\langle prefix \rangle@\langle family \rangle@save$  and also makes global pointer entries\* of the affected keys into the container. The effects of the new feature are illustrated by the following examples. Depending on application, this new feature may be more attractive than the traditional one implemented via setkeys. One obvious advantage of the new system emanates from the fact that some keys do not have default values.

# 11.1 Examples

#### 11.1.1 Legacy xkeyval pointer features

The following provide examples of legacy pointer features of the xkeyval package (key pointers at key setting time):

Example

```
561
562
```

```
\savekeys[KV]{fam}{keya,<mark>\global{</mark>keyb}}
\gsavekeys[KV]{fam}{keyc,keyd,<mark>\global</mark>{keye}}
```

<sup>\*</sup>By global pointer entry we mean an entry like  $\global{keya}$  for keya into the container XKV@(prefix)@(family)@save.

```
\frac{563}{564}
```

```
\setkeys[KV]{fam}{\gsavevalue{keyd}=yyy,
   keye=\usevalue{keyd}}
```

If we had included \global{keyb} in \gsavekeys of macro line 562, its entry in \savekeys would have been overwritten, since keys in the container \XKV@KV@fam@save normally get overwritten if they have the same name. The macro \gsavekeys ensures the global definition of \XKV@KV@fam@save when the keys keyc, keyd and keye are being included, while \global{keyb} ensures that, when keyb is used in a \setkeys command, its value will be saved globally to \KV@fam@keyb@value. When the keys keyc and keyd are set, their values will be saved locally, even though the container \XKV@KV@fam@save was defined globally when the keys keyc and keyd were inserted. However, when keys keyb and keye are set, their values will be saved globally (even though keyb appears in \savekeys and not in \gsavekeys).

The pointer \gsavevalue{keyd} of macro line 563 will ensure that the value of keyd is saved globally to \KV@fam@keyd@value at \setkeys.

## 11.1.2 Extensions by skeyval package

The following provide examples of new pointer features enabled by the skeyval package (key pointers at key definition time):

	Example
565	\define@key[KV]{fam}{\savevalue{keya}}[xxx]{\def\x{*#1*}}
566	<pre>\newordkey[KV]{fam}{\gsavevalue{keyb}}[zzz]{\def\x{=#1=}}</pre>
567	<pre>\newtogkey+[KV]{fam}[mp@]{\savevalue\uservalue{toga}}[true]%</pre>
568 569	{ \iftog{mp@toga}{\def\x{#1}}{}%
570 571	<pre>}{%   \@latex@error{Value '#1' not valid}\@ehc</pre>
572	}
573 574	<pre>\define@cmdkey[KV]{fam}[mp@]{\uservalue\savevalue{keyc}}% [www]{\def\x{#1}}</pre>
575 576	<pre>\newboolkey+[KV]{fam}[mp@]{\gsavevalue\uservalue{boola}}% [true]{%</pre>
577	\ifmp@boola\def\x{#1}\fi
578 579	<pre>}{%   \@latex@error{Value '#1' not valid}\@ehc</pre>
580	}
581 582	<pre>\define@cmdkey[KV]{fam}[mp@]{\guservalue\savevalue{keyd}}% [www]{\def\x{#1}}</pre>
583	<pre>\newchoicekey*+[KV]{fam}{\guservalue\gsavevalue{align}}%</pre>
584	[\val\nr]{center,right,left}[center]%

```
٢%
585
         \ifcase\nr\relax
586
           \def\@align{\centering}%
587
         \or
588
           \def\@align{\flushright}%
589
         \or
590
           \def\@align{\flushleft}%
591
         \fi
592
      }{%
593
         \@latex@error{Inadmissible value '#1' for align}\@ehc
594
      7
595
      \setkeys[KV]{fam}{keya=Hello World,keyb=\usevalue{keya}}
596
```

With the new mechanism of the skeyval package, the \gsavevalue pointer in the command on macro line 566 will ensure that \global{keyb} (not keyb) is inserted in the container \XKV@KV@fam@save and that this container is updated globally after \global{keyb} has been inserted. At \setkeys, in view of the entry \global{keyb}, the value of keyb will be saved globally. The same applies to keys boola and align. This thus has a double effect. Keys keyc and keyd will be saved locally.

# 12 Setting Keys: LIST Normalization

We have redefined the \setkeys command of the xkeyval package in two respects: firstly to accommodate the use of the \skif, \skifx, \skelse, and \skfi macros of Subsection 7.5.2, and secondly to automatically convert double (or even multiple) commas and equality signs inadvertently submitted by the user into single comma and single equality sign. The following exaggerated example depicts the difficulties that might arise and which we wish to address:

597 598

599

```
Example\define@key[KV]{fam}{width}[1cm]{}\define@key[KV]{fam}{color}[black]{}\setkeys[KV]{fam}{width= =2cm, ,,color, == = =,green}
```

Here, the legacy \setkeys will give the value nil to the key width, and the default value of the key color, if it was specified at key definition time, will be given to the key color. Some of the mistakes (especially spurious values without keys) can disrupt a compilation run, while some (multiple commas and equality signs) will not be fatal to compilation but may lead to bizarre results of subsequent calculations. Mistakes of this kind can, surprisingly, be difficult to trace. The extra spaces and multiple commas aren't as serious as the multiple equality signs and values without keys, but we have taken care of all peculiar situations in the new \setkeys. Multiple commas, equality signs, and spaces are now detected and reduced appropriately: that is what we mean by key-value *list normalization*. We have adopted the premise that ",=" (comma followed by equal) and "=," (equal followed by comma) are both most likely to mean

"=" (equal). In the unlikely event that this premise fails, then the user may get tricky errors if he makes this type of mistake.

If, for any reason, the user needs to pass keys with ",=" and/or "=,", then he may separate the comma from the equality sign with {}, e.g., as in

600

Example

\setkeys[KV]{fam}{width=2cm,head={},tail=not measured},

which shows that the value of the key head is \empty, a valid and better assignment.

# 13 MISCELLANEOUS MACROS

This package is predominantly about  $\text{IAT}_{\text{E}}X$  keys and their efficient creation and management, but it also contains many commands for general  $\text{T}_{\text{E}}X$  programming, such that a package author may not need to redefine most of them or load some other packages to access those commands. Some of the available commands are described in this section. The index provides a comprehensive quick resource locator for the commands.

## Defining new commands

The following are provided in the skeyval package but you're advised to use the \TestProvidedCommand macro (described below) to test that you are really using the \newdef of the skeyval package:

601 602

603

604

These commands adopt TEX's syntax and accept parameter delimiters. They are both robust. The unstarred variant produces long macros. The command  $\newdef$  is defined in the skeyval package only if it hasn't been defined by a previously loaded package; the command  $\SKV@newdef$ , on the other hand, is always available. If (cs) was previously defined, both  $\SKV@newdef$  and  $\newdef$  will issue an error.

#### Defining robust commands

These use  $\varepsilon$ -TEX's \protected prefix to provide something resembling LATEX's \DeclareRobustCommand whilst conforming to TEX's \def interface. The unstarred variants produce long macros. These commands accept parameter delimiters and are all robust. The command \robustdef is defined in the skeyval

package only if it hasn't been defined by a previously loaded package; the command SKV@robustdef, on the other hand, is always available. If  $\langle cs \rangle$  was previously defined, both SKV@robustdef and robustdef will issue an error. You can use the above TestProvidedCommand to check whether or not you are using the robustdef of the skeyval package.

TEX-like \providecommand

	Macro
05	$SKV@providedef*(cs)(parameters){(replacement text)}$
06	$\providedef (cs) \langle parameters \rangle \{ \langle replacement text \rangle \}$
07	$SKV@providerobustdef*(cs)(parameters){(replacement text)}$
08	$\providerobustdef \\ \textbf{(cs)} \\ parameters \\ \textbf{(replacement text)} \\ \textbf{(cs)} \\ \textbf{(replacement text)} \\ \textbf{(cs)} \\ ($

These emulate LATEX's \providecommand, but they conform to TEX's \def interface. The unstarred variants produce long macros. These commands accept parameter delimiters and are all robust. The commands \providedef and \providerobustdef are defined in the skeyval package only if they haven't been defined by a previously loaded package; the commands \SKV@providedef and \SKV@providerobustdef, on the other hand, are always available. Macros defined by \SKV@providerobustdef and \providerobustdef are robust, while those defined by \SKV@providedef and \providerobustdef are nonrobust. If  $\langle cs \rangle$  was previously defined, all these commands will simply ignore the new definition and enter a message to this effect in the log file (if the package option verbose is selected).

\requirecmd

609 610

This is explained in Subsection 5.1. If  $\langle cs \rangle$  is already defined, \requirecmd checks if the new and old definitions are identical. If they aren't, a warning message is logged in the transcript file (if the package option verbose is selected) and the new definition is aborted.

# Testing "provided" commands

611	\TestProvidedCommand(	$\langle cs \rangle \{ \langle true \rangle \}$	$text$ {{false	text

This can be used to test whether or not one is using the  $\newdef$  (or any other "provided" command) of the skeyval package. Here  $\langle cs \rangle$  is either  $\newdef$  or any "provided" command. In fact, if you define any command using the macro  $\SKV@providedef$  or  $\SKV@providerobustdef$  (see below), you can verify by  $\TestProvidedCommand$  whether or not the new definition is the one in effect.

```
Example

612 \SKV@providerobustdef*\newcmd{\newcommand}

613 \TestProvidedCommand\newcmd{%

614 \@latex@info{`\string\newcmd' is `\string\newcommand'}%

615 }{%

616 \@latex@error{`\string\newcmd' isn't %

617 `\string\newcommand'}\@ehd

618 }
```

# Declaring new unique variables collectively

New definable variables can be introduced in sets by the following commands.

This provides, for each member of the comma-separated list  $\langle boolean list \rangle$ , a new native-boolean register if the register didn't already exist, otherwise an error is flagged. Each member of  $\langle boolean list \rangle$  is prefixed with  $\langle prefix \rangle$  upon definition. The optional  $\langle state \rangle$  can be either true or false.

```
Example
```

```
620
621
622
```

623

Notice that members of the list (boolean list) don't have \if in their names.

624

 $\label{eq:logsloss} $$ NewTogs[(optional prefix)]{(tog list)}[(optional state)] $$$ 

This provides a new toggle register for each member of the comma-separated list  $\langle tog list \rangle$  if the register didn't already exist, otherwise an error is flagged. Each member of  $\langle tog list \rangle$  is prefixed with  $\langle prefix \rangle$  upon definition. The optional  $\langle state \rangle$  can be either true or false.

```
      Example

      625

      626

      626

      627

      \togtrue{toga} \newtog{togb} \newtog{togc}

      628

      628

      NewTogs{togd}

      629

      NewToks[⟨optional prefix⟩]{⟨toks list⟩}
```

This provides a new token list register for each member of the comma-separated list  $\langle toks list \rangle$  if the register didn't already exist, otherwise an error is flagged. Each member of  $\langle toks list \rangle$  is prefixed with  $\langle prefix \rangle$  upon definition.

This provides a new counter register for each member of the comma-separated list  $\langle \text{counter list} \rangle$  if the register didn't already exist, otherwise an error is flagged. Each member of  $\langle \text{counter list} \rangle$  is prefixed with  $\langle \text{prefix} \rangle$  upon definition.

Macro

634 \NewDimens[(optional prefix)]{(dimen list)}

This provides a new dimension register for each member of the comma-separated list  $\langle \texttt{dimen list} \rangle$  if the register didn't already exist, otherwise an error is flagged. Each member of  $\langle \texttt{dimen list} \rangle$  is prefixed with  $\langle \texttt{prefix} \rangle$  upon definition.

635

This allocates a new box register for each member of the comma-separated list  $\langle box list \rangle$  if the box register didn't already exist, otherwise an error is flagged. Each member of  $\langle box list \rangle$  is prefixed with  $\langle prefix \rangle$  upon definition.

```
Example
Example

NewBoxes[box]{a,b,c}
→ \newbox\boxa \newbox\boxb \newbox\boxc
NewBoxes{boxd} → \newbox\boxd

NewWrites[(optional prefix)]{(stream list)}

This allocates a new output stream for each member of the comma-separated list
(stream list) if the stream didn't should need a suit at herein an amount of the need a suit at herein and a suit at herein at her
```

This allocates a new output stream for each member of the comma-separated list  $\langle \texttt{stream list} \rangle$  if the stream didn't already exist, otherwise an error is flagged. Each member of  $\langle \texttt{stream list} \rangle$  is prefixed with  $\langle \texttt{prefix} \rangle$  upon definition.

```
    640
    \NewWrites[write]{a,b,c}

    641
    → \newwrite\writea \newwrite\writeb \newwrite\writec
```

#### 642

## $\mathbb{V} = \mathbb{V}$

All the macros \NewIfs, \NewToks, \NewCounts, \NewDimens, \NewBoxes, and \NewWrites are non-outer, unlike their primitive counterparts.

## Defining new names

		Macro	
643	$SKV@csdef+{(name)}{(definition)}$		
644	$SKV@csgdef+{(name)}{(definit)}$	$:ion\rangle$ }	
645	\SKV@csedef+{{name}}{{definit	$:ion\rangle$	
646	$SKV@csxdef+{(name)}{(definit)}$	;ion)}	

The unsigned variants of these turn  $\langle name \rangle$  into a control sequence in terms of  $\langle definition \rangle$  whether or not the control was already defined. No error or warning messages are issued. The plus (+) variants turn  $\langle name \rangle$  into a control sequence if it wasn't already defined; if it is already defined, an error message is flagged. These derive from a concept based on that of  $\langle newcommand$ , but (i)  $\langle relax'ed$  commands are considered undefined in this regard, and (ii) these commands retain the powerful machinery of plain T<sub>F</sub>X.

**Note:** The skeyval package contains other undocumented tools for defining new commands.

#### Name use

Macro

 $_{647}$  \SKV@csuse{ $\langle name \rangle$ }

 $SKV@newlet{\langle cs1 \rangle}{\langle cs2 \rangle}$ 

 $\mathbb{E}_{cs1}$ 

This is similar to  $\square T_E X$ 's legacy \@nameuse but returns \@empty (instead of an error) if  $\langle name \rangle$  is undefined. This is due originally to etoolbox package.

## \let assignments

Macro

648 649

These assign  $\langle cs2 \rangle$  to  $\langle cs1 \rangle$  if  $\langle cs2 \rangle$  exists and if  $\langle cs1 \rangle$  isn't already defined, otherwise an error is flagged. The command  $\NewLet$  is defined in the skeyval package only if it hasn't been defined by a previously loaded package; the command  $\SKV@newlet$ , on the other hand, is always available. You can use  $\TestProvidedCommand$  (macro line 611) to test whether or not you are using the  $\NewLet$  command of the skeyval package.

 Macro

 650
 \SKV@cslet{(name)}{(cs)}

 651
 \SKV@letcs{(cs)}{(name)}

 652
 \SKV@csletcs{(name)}{(name)}

These perform **\let** assignments if the second argument is defined, otherwise an error message is flagged. The notation  $\langle cs \rangle$  means a control sequence, and  $\langle name \rangle$  means a control sequence name.

 Macro

 653
 \SKV@cslet\*{(name)}{(cs)}

 654
 \SKV@letcs\*{(cs)}{(name)}

 655
 \SKV@csletcs\*{(name)}{(name)}

These perform **\let** assignments whether or not the second argument is defined. If the second argument is undefined, the first remains undefined and the hash table is not filled.

# Number and dimension expressions

Macro

656

657

 $SKV@numdef+?{(num)}{(expression)}$ 

 $\label{eq:skV@numdef} $$ (num) from (expression) using $$ c-TEX's \numexpr. If (num) was previously undefined, it is first initialized with \newcount before the expression is built. If you do \SKV@numdef\x{1+2+3}, you would need to prefix \x with \the or \number in expressions. Expressions defined by \SKV@numdef can be used with TEX's operators such as \advance or \multiply and $$ c-TEX's \numexpr operator. $$ (numexpr operators).$ 

The plus sign (+) means that \SKV@numdef takes a control sequence name instead of a control sequence, while the question mark (?) implies that the macro \SKV@numdef effects a global assignment which can thus escape local groups.

 $\label{eq:skv@dimdef} $$ dim \ defines \ dim \ from \ expression \ using $$ c-T_EX's \ dim expr. If \ dim \ was previously undefined, it is first initialized with \newdimen before the expression is built. If you do \SKV@dimdef \x{1pt+2pt+3pt}, you would need to prefix \x with \the in expressions. Expressions defined by \SKV@dimdef \can be used with $$ c-T_EX's \dim expr operator. $$$ 

The plus sign (+) means that \SKV@dimdef takes a control sequence name instead of a control sequence, while the question mark (?) implies that the macro \SKV@dimdef effects a global assignment which can thus escape local groups.

# Verifying definability

Macro

658

 $SKV@ifdefinable(cs){(function)}$ 

IATEX kernel's \@ifdefinable fills up the hash table and also considers commands that are \relax'ed as defined. Moreover, if the command being tested ( $\langle cs \rangle$  in the above example) is definable, the \@ifdefinable macro begins executing  $\langle function \rangle$  while still in the \if ...\fi conditional. You can't do \let\ifabc\iftrue in such conditionals. The command \SKV@ifdefinable, which is robust, seeks to avoid these problems.

Macro

#### 659 $\SKV@ifdefinable@n{(list)}$

F

The macro \SKV@ifdefinable@n accepts a comma-separated list of control sequence *names* whose definability are to be tested. It should be noted that the macro \SKV@ifdefinable@n doesn't accept (function), unlike the above \SKV@ifdefinable. The aim of \SKV@ifdefinable@n is simply to test the definability of instances/members of (list).

Example

Macro

660

\SKV@ifdefinable@n{ax,ay,az}

661

 $SKV@ifnew*+[(optional parser)]{(list)}$ 

The macro SKV@ifnew is similar to, but more versatile, than the command SKV@ifdefinable@n. The star sign (\*) in SKV@ifnew indicates that  $\langle list \rangle$  is available in a macro, say mylist; and the plus sign (+) shows SKV@ifnew that members of  $\langle list \rangle$  (or mylist) are control sequence names, otherwise they are control sequences (see examples below). The default value of the optional  $\langle parser \rangle$  is "," (comma). The macro SKV@ifnew doesn't execute any  $\langle function \rangle$ . Both SKV@ifdefinable@n and SKV@ifnew are robust.

Example

662	\def\mylist{ax,ay,az}
663	\SKV@ifnew*+[,]\mylist
664	\SKV@ifnew*+\mylist
665	\SKV@ifnew+{ax,ay,az}
666	\SKV@ifnew{\ax\ay\az}
667	\def\my@list{\ax\ay\az}
668	\SKV@ifnew*\my@list
669	\def\my@@list{ax;ay;az}
670	\SKV@ifnew*+[;]\my@@list
671	$\SKV@ifnew\ax \rightarrow \SKV@ifnew+{ax} \rightarrow \SKV@ifdefinable@n{ax}$

# Verifying the status of variables

These use  $\varepsilon$ -T<sub>E</sub>X's facilities to test the existence of the control sequence  $\langle cs \rangle$  or control sequence name  $\langle name \rangle$ . These commands aren't robust and may be used to determine the current state of the macro replacement text, if such replacement text contains these commands. \relax'ed macros are considered undefined by *all* these commands. To test if a macro is \relax'ed, use the following commands:

	Macro
676	$SKV@ifrelax(cs){(true)}{(false)}$
677	$SKV@ifcsrelax{\langlename\rangle}{\langletrue\rangle}{\langlefalse\rangle}$
	Macro
678	$\SKV@ifdefax(cs){(defined)}{(relaxed)}{(undefined)}$
679	$\SKV@ifcsdefax{\langlename\rangle}{\langledefined\rangle}{\langlerelaxed\rangle}{\langleundefined\rangle}$

These test if  $\langle cs \rangle$  or  $\langle name \rangle$  is defined, relaxed, or undefined. In using these three-valued logical tests, it is often easy to forget to include the null state (i.e.,  $\langle undefined \rangle$ ) because  $T_EX$  is dominated by two-valued logical tests.

## Undefining macros

Macro

680

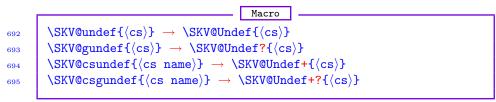

\SKV@Undef\*+?[{optional parser}]{{cs}}

This undefines the macros or control sequence names in the list  $\langle cs \rangle$  (of nil, one or more elements) such that T<sub>E</sub>X will subsequently consider each element undefined. The star sign (\*) indicates that  $\langle cs \rangle$  is given as a macro whose *contents* are to be individually undefined, and the plus sign (+) shows that  $\langle cs \rangle$  is made up of *control sequence names* instead of control sequences. The question mark (?) directs  $\langle SKV@Undef$  to *globally* undefine all the control sequences or names in  $\langle cs \rangle$ . Control sequence names are to be separated by the parser; control sequences shouldn't be separated. The default value of the  $\langle parser \rangle$  is "," (comma). The command  $\langle SKV@Undef$  is robust (it will thus not expand in expansion contexts), but fragile arguments would need to be protected in expansion contexts.\*

<sup>\*</sup>Macros such as \@ifnextchar, \@ifstar, and those involving optional arguments normally can't be evaluated in expansion contexts. The same applies to the skeyval package macros with optional arguments. The etextools package introduced expandable variants of these commands, but in the contexts these commands are employed in the skeyval package,

The following non-generic variants avoid the above complications of signs, but they don't take lists:

# **Expansion control**

Macro

Macro -

696

697

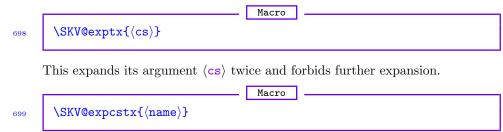

This expands its argument  $\langle \mathtt{cs} \rangle$  once and forbids further expansion.

\SKV@expcsox{(name)}

 $SKV@expox{(cs)}$ 

the expandable variants aren't particularly advantageous. The main reason is that some of our internal macros (e.g., looping macros) aren't amenable to full expansion anyway. Actually, the skeyval package provides the fully expandable variants (\SKV@TestOpt, \SKV@IfStar, \SKV@IfPlus, and \SKV@IfAsk) of the non-expandable commands \SKV@testopt, \SKV@ifstar, \SKV@ifplus, and \SKV@ifask. The commands \SKV@ifask and \SKV@IfAsk look for an optional question mark (?).

This is similar to SKV@expox but accepts control sequence name (name) instead of control sequence.

This is similar to SKV@exptx but accepts control sequence name (name) instead of control sequence.

Macro

700

SKV@expargs(n)(function)(arg1)(arg2)(@nil)

IATEX's \@expandtwoargs is often used as a utility macro to expand two arguments  $\langle arg1 \rangle$  and  $\langle arg2 \rangle$  in order to execute  $\langle function \rangle$ . The command \SKV@expargs, on the other hand, accepts up to four expansion types, signified by  $\langle n \rangle$ , which runs from 0 to 3:

- a) If  $\langle n \rangle$  is 0, then  $\langle arg2 \rangle$  is empty and only  $\langle arg1 \rangle$  will be expanded before  $\langle function \rangle$  is executed.
- b) If (n) is 1, then both (arg1) and (arg2) are nonempty but only (arg2) will be expanded before (function) is executed.
- c) When  $\langle n \rangle$  is 2, then both  $\langle arg1 \rangle$  and  $\langle arg2 \rangle$  are nonempty and both will be expanded before  $\langle function \rangle$  is executed. This is equivalent to LATEX's  $\langle @expandtwoargs. \rangle$
- d) If (n) is 3, then both (arg1) and (arg2) are nonempty but only (arg1) is expanded before (function) is executed.
- e) If  $\langle n\rangle$  isn't in the list {0,1,2,3}, then an error message is flagged.

Because  $\langle arg2 \rangle$  is delimited, it can be empty. The command SKV@expargs can be used to save expandafter's, but caution should be exercised in deploying it: for example, the edef it uses may expand too deeply in some cases. Also, precaution may be necessary when the expanded arguments ( $\langle arg1 \rangle$  and/or  $\langle arg2 \rangle$ ) involve the T<sub>E</sub>X primitive if. When invoking SKV@expargs, the macros SKV@expox and SKV@exptx can be used to control the level of expansion.

Some trivial examples follow:

```
Example
```

```
701 \SKV@expargs{0}{\def\tempc#1#2}{\def\noexpand##1{##2}}\@nil
702 \tempc\tempa{aa}
703 \tempc\tempb{abcaaabbccbca}
704 \SKV@expargs{2}\SKV@in@\tempa\tempb\@nil
705 \show\ifin@
```

These expressions show how \SKV@expargs can be used to economize on chains of \expandafter's. The expression on macro line 701, for example, isn't directly possible by \@expandtwoargs.

# Checking values of choice keys

Choice keys should, by definition, have preordained values. This requirement can be useful even for non-choice keys.

Macro

706

 $\label{eq:skv@checkchoice{value}}{\langle \texttt{altlist} \rangle}{\langle \texttt{true} \rangle}{\langle \texttt{false} \rangle}$ 

This is an enhanced form of xkeyval package's XKV@checkchoice. It checks if the user-submitted  $\langle value \rangle$  of a key (say,  $\langle keya \rangle$ ) is in the list  $\langle altlist \rangle$ . It executes  $\langle true \rangle$  if  $\langle value \rangle$  is found in  $\langle altlist \rangle$  and  $\langle false \rangle$  otherwise. Additionally, it returns  $\langle val$  for the expanded value of  $\langle value \rangle$  and  $\langle nr$  for the numerical order of  $\langle val$  in the list  $\langle altlist \rangle$ . If  $\langle value \rangle$  isn't found in  $\langle altlist \rangle$ , then  $\langle nr$  will return -1. If  $\langle value \rangle$  and  $\langle altlist \rangle$  are buried in macros, the macros are fully expanded before the search for  $\langle value \rangle$  in the list  $\langle altlist \rangle$ is effected. In that case,  $\langle val will hold the expanded form of <math>\langle value \rangle$  and can be used in subsequent computations. Choice keys do accept macros as values, but such values aren't directly suitable for matching against the contents of  $\langle altlist \rangle$ . For example,  $\langle altlist \rangle$  may be the set {left,right,center}, but given as a macro  $\langle @altlist, while \langle value \rangle$  is given as  $\langle elf \langle value \langle center \rangle$ . Obviously,  $\langle @value contains one of the elements of <math>\langle altlist \rangle$ , but choice keys won't know this without the expansion of both  $\langle @altlist$  and  $\langle @value$ . This is raison d' $\hat{e}$  tre of the  $\langle SKV@checkchoice macro.$ 

Moreover, \SKV@checkchoice can be used in the definition of non-choice keys. In the following example we check the value of an *ordinary* key by means of \SKV@checkchoice:

Example

```
\def\@altlist{left,right,center}
707
      \newordkey[KV]{fam}{keya}[true]{%
708
        \SKV@checkchoice{#1}{\@altlist}{%
709
           \ifcase\nr\relax
710
             \edef\tempa##1##2{##1===\val===##2}%
711
           \or
712
             \edef\tempa##1##2{##1***\val***##2}%
713
           \or
714
             \edef\tempa##1##2{##1+++\val+++##2}%
715
           \fi
716
        }{%
717
           \@latex@error{Wrong value for 'keya'}\@eha
718
        }%
719
      }
720
      \def\@value{center}
721
      \setkeys[KV]{fam}{keya=\@value}
722
```

The reader may wish to do \show\tempa to see what \tempa gets upon setting the key keya.

# Testing for substring Macro $SKV@in@{(substring)}{(string)}$ 723 This is similar to the LATEX kernel's \in@{(substring)}{(string)} which tests if (substring) is in (string), but the present test avoids the problem of false result, which is typified by the following test: Example \in@{aa}{ababba} 724 This incorrectly returns \ifin@ as \iftrue. The macro \SKV@in@, on the other hand, correctly gives \ifin@ as \iffalse in this case. The command \SKV@in@ is robust. Macro 725 In this case the returned boolean is the toggle switch (in@) instead of the kernel's (in@) switch which is used as ifin@. The toggle (in@) can be used in the following way and in other manners that toggles can be employed: Example $\inf \{ in0\} \{ \langle true \rangle \} \{ \langle false \rangle \}.$ 726 The command \in@tog is robust. Macro

727

Sometimes you want to use the LATEX kernel's \in@{{substring}}{{string}} to test if {substring} is in {string} irrespective of their catcodes. The robust command \in@tok{{substring}}{{string}} makes this possible, and eliminates the tokens that would have been necessary if the user was required to first detokenize the two arguments. It returns the same switch \ifin@ as the

first detokenize the two arguments. It returns the same switch \ifin@ as the kernel's  $\in@{\langle substring \rangle}{\langle string \rangle}$ . Actually, it calls SKV@in@ to avoid false returns.

# Testing equality of strings

	Macro
728	$\SKV@ifstrequal{\langle string1 \rangle}{\langle string2 \rangle}{\langle true \rangle}{\langle false \rangle}$
729	$\SKV@ifstrnotequal{\langle string1 \rangle}{\langle not true \rangle}{\langle not false \rangle}$

730 731

```
\SKV@oifstrequal{\langle string1 \rangle}{\langle string2 \rangle}{\langle true \rangle}{\langle false \rangle} \\SKV@xifstrequal{\langle string1 \rangle}{\langle string2 \rangle}{\langle true \rangle}{\langle false \rangle}
```

In order to properly test the equality of strings, it may be necessary to remove leading and trailing spaces before the test. Such spaces may have cropped into the strings from input or from pre-processing and may invalidate the test. The macro  $\SKV@ifstrequal$  takes care of such situations. It executes  $\langle true \rangle$  if  $\langle string1 \rangle$  is equal (character code wise) to  $\langle string2 \rangle$ , and  $\langle false \rangle$  otherwise. Both  $\langle string1 \rangle$  and  $\langle string2 \rangle$  are detokenized before the test. The macro  $\SKV@oifstrequal$  is similar to  $\SKV@ifstrequal$  but first expands its arguments (the two strings  $\langle string1 \rangle$  and  $\langle string2 \rangle$ ) once before the test. The macro  $\SKV@ifstrequal$  first expands its arguments fully before the test.

# Testing for empty or blank

	Macro
732	$SKV@ifempty{(token)}{(true)}{(false)}$
733	$\SKV@ifnotempty{(token)}{(not true)}{(not false)}$
734	$SKV@oifempty{(token)}{(true)}{(false)}$
735	$SKV@xifempty{(token)}{(true)}{(false)}$

These yield  $\langle true \rangle$  if  $\langle token \rangle$  is empty, and  $\langle false \rangle$  otherwise. In the command  $\langle SKV@ifempty, \langle token \rangle$  isn't expanded before the test; in the command  $\langle SKV@oifempty, \langle token \rangle$  is expanded once before the test; in the command  $\langle SKV@xifempty, \langle token \rangle$  is fully expanded before the test.

	Macro
736	$SKV@ifblank{\langle token \rangle}{\langle true \rangle}{\langle false \rangle}$
737	$SKV@ifnotblank{(token)}{(not true)}{(not false)}$
738	$SKV@oifblank{(token)}{(true)}{(false)}$
739	$SKV@xifblank{(token)}{(true)}{(false)}$

These macros test if the argument is blank or not. The first of these is from ifmtarg package. \SKV@oifblank expands its argument once before the test, while \SKV@xifblank expands its argument fully before the test.

# Verifying draft and final options

	Macro
740	$SKV@ifdraft{\langle true \rangle}{\langle false \rangle}$
741	\SKV@ifnotdraft{{not true}}{{not false}}
742	$SKV@iffinal{(true)}{(false)}$
743	$SKV@ifnotfinal{(not true)}{(not false)}$
744	\iftog{draft}{(true)}{(false)}
745	$ifnottog{draft}{\langle not true \rangle}{\langle not false \rangle}$
746	$iftog{final}{\langle true \rangle}{\langle false \rangle}$
747	$\inf \{ not true \} \{ (not false ) \}$

These execute (true) or (false) depending on whether draft or final appears as true in the options list of \documentclass or \usepackage{skeyval}. The default is that final is true, which implies that draft is false by default. The keys draft and final are complementary native-boolean keys (see Section 4), which reduces the risk of mixing them. These commands are robust.

Macro

748\ifdraft{ $\langle true \rangle$ }{ $\langle false \rangle$ }749\ifnotdraft{ $\langle not true \rangle$ }{ $\langle not false \rangle$ }750\iffinal{ $\langle true \rangle$ }{ $\langle false \rangle$ }

751 \ifnotfinal{(not true)}{(not false)}

These are also defined in the skeyval package, but because packages such as ifdraft package already exist, the skeyval package defines them only if they haven't already been defined. If they existed before skeyval package is loaded, they aren't redefined, and (if the package option verbose is selected) a warning is logged in the transcript file to indicate that the definition being used isn't from the skeyval package. The warning is logged only once. I am aware of the existence of only \ifdraft outside the skeyval package: therefore, the definition of \ifdraft is deferred until \AtBeginDocument. You can use \TestProvidedCommand to check the version of the \ifdraft that you are using.

# Verifying dvi and pdf modes

```
    Macro

    752
    \SKV@ifpdf{\true}}{\false}

    753
    \SKV@ifnotpdf{\not true}}{\not false}

    754
    \iftog{pdf}{\true}}{\true}}{\true}}

    755
    \ifnottog{pdf}{\not true}}{\true}}
```

These execute  $\langle true \rangle$  or  $\langle false \rangle$  depending on whether dvi or pdf output is being produced. These commands are robust and may be used in expansion contexts.

Macro

756 757

```
\ifpdf{\true}}{\false}}
\ifnotpdf{\not true}}{\not false}}
```

These are available only if they haven't been previously defined by another package. If they existed outside the skeyval package, a warning is logged in the transcript log file (if the package option verbose is selected), but only once, and the commands are not redefined. In particular, the above \ifpdf is available only at \AtBeginDocument and is defined only if it doesn't already exist. The reason is that the popular hyperref package loads the ifpdf package and the ifpdf package will abort if it detects that \ifpdf has been defined by a package loaded earlier.

Note: The \ifpdf command of the ifpdf package is used in the \if ... \else ... \fi conditional, while the above \ifpdf command is used as indicated above. You can use the \TestProvidedCommand macro to check the version of the \ifpdf that you are using.

# Tests related to package loading

	Macro
	$\label{eq:linear} \label{linear} \$
759	$\label{eq:linear} \label{eq:linear} \label{linear} linear$

These executes (true) if the date of the current/loaded version (package) is greater than or equal to (date). This is similar to IATEX's \@ifpackagelater but, unlike the latter, both \@ifpackagecurrent and \@ifpackagenotcurrent are robust. My main reason for these commands is that the nomenclature \@ifpackagelater is subject to the wrong interpretation of being space (rather than time) related.

#### 760

Macro

This executes  $\langle code \rangle$  only after  $\langle package \rangle$  has been loaded. This has been optimized from the afterpackage package to avoid filling up the hash table with hooks that are relax'ed or indeed undefined, and to warn the user if  $\langle package \rangle$  was not eventually loaded. If at the start of document,  $\langle package \rangle$  has not been loaded, a warning message is entered in the log file. Use the following \@ensurepackageloaded macro if you really need an error message in this case.

Macro

761

 $\mathbb{Q}_{ensurepackageloaded}$ 

This will issue an error at start of document if any member of the commaseparated list  $\langle packages \rangle$  wasn't loaded before then. This command can be used to signpost those packages that must be loaded later.

# Commands restricted to package and preamble

The LATEX kernel's macro \@onlypreamble accepts only one command at a time (i.e., you can't give it a list of preamble commands in one go), and the error message \@notprerr is not that precise, since it doesn't indicate the command that has been wrongly placed in the document's body. The use of \@onlypreamble in a style or class file can be monotonous if the file has many preamble commands. The macro \SKV@onlypreamble takes a no-comma (list) of commands at once

and gives precise error messages related to the incorrectly located commands. The  $\langle list \rangle$  may be populated with nil, one, or more control sequences, e.g.,

Example

#### \SKV@onlypreamble{\macroa \macrob \macroc}

All preamble commands can be collected together in one \SKV@onlypreamble, preferably at the end of the style or class file.

The function \SKV@onlypackage may be used to restrict commands to packages only. For example, the following restricts the command \x to packages only:

Example

765

764

\def\x#1{\SKV@onlypackage\usearg{#1}}

# Extended \aftergroup and \afterassignment

	Macro
766	$SKV@aftergroup{(code)}$
767	$SKV@aftergroup*{(code)}$
768	$SKV@afterassignment{(code)}$
769	$SKV@afterassignment*{(code)}$

 $T_{E}X$ 's \aftergroup and \afterassignment don't accept arbitrary code. These commands execute the arbitrary  $\langle \text{code} \rangle$  after a group or assignment. The starred variants expand  $\langle \text{code} \rangle$  once before the assignment or before exiting the group. These commands don't accumulate the group and assignment counters indefinitely: the counters are initialized after each group or each assignment.

Some examples follow:

```
Example
      \let\gobblex\@firstofone
770
      \def\protected@mydef{%
771
         \let\@@protect\protect
772
         \let\protect\@unexpandable@protect
773
         \SKV@afterassignment{%
774
          \restore@protect
775
          \let\gobblex\@gobble
776
         }%
777
         \edef
778
      }
779
      \def\aa{aaa} \def\bb{bbb} \def\xx{xxx} \def\yy{yyy}
780
      \begin{document}
781
      \begingroup
782
        \SKV@aftergroup{\par\aa***\bb}%
783
        \SKV@aftergroup{\par\bb***\aa}%
784
        \begingroup
785
```

- 786 \SKV@aftergroup{\par\xx+++\yy}%
- 787 \SKV@aftergroup{\par\yy+++\xx}%
- 788 \endgroup
- 789 \endgroup
- 790 \end{document}

# List processing

791 792

793

794

These are fast for-loops that accept general list parsers and allow for list breaks, as well as give the remainder of the list if a break occurs within the list. Elements of  $\langle list \rangle$  are stored in  $\langle cmd \rangle$ , and  $\langle function \rangle$  is executed for each element of  $\langle list \rangle$ . The  $\langle list \rangle$ , which is populated by parser-separated elements, is not expanded before the iteration, but  $\langle listcmd \rangle$  is expanded once before the commencement of the loop. The list parser is dynamically declarable via

 Macro

 \SKV@CommandGenParser{(parser)} or

 \skvoptions{genparser=(parser)},

Also, these iteration macros use the more powerful \SKV@ifblank to check whether or not (list) is empty or blank. The commands \SKV@for@a and \SKV@for@b are robust, but in expansion contexts, both (cmd) and (function) will need to be protected. In the \SKV@for@b command, (listcmd) is expanded once before the iteration commences. The (parser) persists in effect until it is changed by another call to \SKV@CommandGenParser or \skvoptions as above.

Note: One snag with a generic list parser like \SKV@CommandGenParser is that the user must always remember to call it and set the right parser before beginning an iteration, otherwise there might be unpleasant results, since a previous call to \SKV@CommandGenParser might have set a parser that is no longer valid. To obviate this type of situation, the following commands are also provided in the skeyval package:

7	9	5
_	_	

Macro

\SKV@for[(parser)]{(list)}(cmd){(function)} \SKV@for\*[(parser)](listcmd)(cmd){(function)}

The (parser) appears as an optional argument in these commands and its default value is "," (comma). These commands allow the user to provide the (parser) with every call. The unstarred and starred versions of \SKV@for are equivalent to \SKV@for@a and \SKV@for@b, respectively. Both sets (\SKV@for@a and \SKV@for@b | \SKV@for and \SKV@for\*) may be needed in different circumstances. In applications where the (parser) is fixed, the commands \SKV@for@a and SKV@for@b are faster than SKV@for and SKV@for\* because in the former cases the  $\langle parser \rangle$  would then need to be set only once: each call to SKV@for or SKV@for\*, whether or not the optional  $\langle parser \rangle$  is provided, resets the  $\langle parser \rangle$ .

The list parser itself is available in  $\parser$ , which can be used in (function). An example follows:

Example

```
797 \SKV@CommandGenParser{;}
798 \SKV@for@a{a;b;c;d}\cmd{\if a\cmd '\cmd'\ is 'a'\parser
799 \else\space '\cmd'\ isn't 'a'\parser\fi}.
```

This list can be broken after, say, elements "a" and "b", as follows:

```
Example

SKV@for@a{a;b;listbreak;c;d}\cmd

{\if a\cmd '\cmd'\ is 'a'\parser\else\space '\cmd'\

so2 isn't 'a'\parser\fi},
```

upon which the remainder of the list is accessible from \SKV@remainder.

803 804

807

808

809

The first of these (i.e., SKV@tfor@a) is equivalent to LATEX kernel's @tfor, which loops over  $\langle list \rangle$  token-wise (character or control sequence token), but these two macros have been prompted by the following rationale. Note that  $\langle list \rangle$  is not a comma-separated list! In SKV@tfor@b,  $\langle listcmd \rangle$  is expanded once before the commencement of the loop. The two commands SKV@tfor@a and SKV@tfor@b are both robust.

The <code>\@break@tfor</code> of the LATEX kernel allows the user to break out of the <code>\@tfor</code> loop but provides no mechanism for saving the remainder of the <code>\list</code> upon breaking the list. Secondly, I have had trouble breaking out of simple <code>\@tfor</code> loops. For example, the following fails: LATEX complains of "extra "fi", the reason being obvious.

```
Example

Ndef\one{One}\def\two{Two}\def\three{Three}

\@tfor\x:=\one\two\@break@tfor\three\do{\x}

Thirdly, if the content of \x above is sanitized/detokenized in the loop be-

fore being used in \function\ (or sanitized in the \function\) itself), then

\@break@tfor can't break the loop. Consider the following:

Example
```

```
\@tfor\x:=\one\two\@break@tfor\three\do{%
    \edef\x{\detokenize\expandafter{\x}}%
}
```

Clearly, \@break@tfor can't break this loop. The macros \SKV@tfor@a and \SKV@tfor@b circumvent these problems. Additionally, they (a) reorder the arguments such that  $\langle list \rangle$  comes before  $\langle cmd \rangle$ , and (b) remove the need for the usual delimitating tokens, thereby making their syntaxes mimic those of \SKV@for@a and \SKV@for@b.

In the following, the remainder of the list (namely, three) can be accessed from the macro  $\SKV@remainder$ :

```
Example

SIO \SKV@tfor@a{\one\two\listbreak\three}\x{%

\edef\x{\detokenize\expandafter{\x}}%

}

SI2 Macro

SI3 \SKV@tfor{{list}}{cmd}{{function}}

SKV@tfor*{listcmd}{cmd}{{function}}
```

These are equivalent to \SKV@tfor@a and \SKV@tfor@b respectively.

# Hook management

Hooking to user-defined macros

```
815
```

This appends  $\langle \text{content} \rangle$  to  $\langle \text{cs} \rangle$ . If  $\langle \text{cs} \rangle$  was previously undefined, it is initialized with  $\langle \text{content} \rangle$ . The star ( $\star$ ) sign directs  $\langle \text{SKV@appto}$  to expand  $\langle \text{content} \rangle$ once before appending  $\langle \text{content} \rangle$  to  $\langle \text{cs} \rangle$ . The plus (+) sign means that  $\langle \text{cs} \rangle$  is a control sequence name instead of a control sequence, while the question mark (?) instructs  $\langle \text{SKV@appto}$  to append  $\langle \text{content} \rangle$  to  $\langle \text{cs} \rangle$  globally (to escape local groups). This command is robust, but fragile arguments must be protected in expansion contexts.

Except for the initialization of undefined  $\langle cs \rangle$ , SKV@appto? is equivalent to  $IAT_FX's \g@addto@macro.$ 

The following non-generic, less powerful, forms of  $\SKV@appto$  are also available, but they don't have the starred ( $\star$ ) variants:

```
Macro
         \geq \langle cs \rangle \{ (content) \}
816
                            SKV@appto(cs){(content)}
                      \rightarrow
817
         gapptomac(cs){(content)}
818
                      \rightarrow \SKV@appto?(cs){(content)}
819
         \csapptomac{\langle name \rangle}{\langle content \rangle}
820
                      \rightarrow \SKV@appto+{\langle name \rangle}{\langle content \rangle}
821
         \csgapptomac{(name)}{(content)}
822
                      \rightarrow \SKV@appto+?{\langle name \rangle}{\langle content \rangle}
823
```

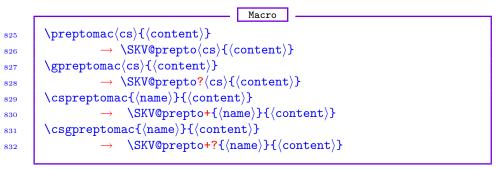

#### 824

\SKV@prepto**\*+?**{cs}{{content}}

This prepends  $\langle \text{content} \rangle$  to  $\langle cs \rangle$ . If  $\langle cs \rangle$  was previously undefined, it is initialized with  $\langle \text{content} \rangle$ . The star ( $\star$ ) sign directs  $\langle \text{SKV@prepto}$  to expand  $\langle \text{content} \rangle$  once before prepending it to  $\langle cs \rangle$ . The plus (+) sign means that  $\langle cs \rangle$  is a control sequence name instead of a control sequence, while the question mark (?) instructs  $\langle \text{SKV@prepto}$  to prepend  $\langle \text{content} \rangle$  to  $\langle cs \rangle$  globally (to escape local groups). This command is robust, but fragile arguments must be protected in expansion contexts.

Macro

Again, the following non-generic versions of  $\SKV@prepto$  are available, but they don't have the starred ( $\star$ ) variants:

833

.....

This adds the contents of the macro  $\langle csb \rangle$  to the list in the container  $\langle csa \rangle$ . The plus sign (+) means that  $\langle csa \rangle$  is a control sequence name, and the question mark (?) directs SKV@addtolist to add the contents of  $\langle csb \rangle$  to  $\langle csa \rangle$  globally (to escape local groups). The optional argument  $\langle parser \rangle$  is the list parser, ie, the separator of the instances in  $\langle csa \rangle$ . Its default value is "," (comma).

#### Package and document hooks

Macro

 $\SKV@AtPackageEnd{ < code > } \\ \\SKV@AtClassEnd{ < code > }$ 

These are the robust versions of the well-known LATEX hooks \AtEndOfPackage and \AtEndOfClass.

 Macro

 836
 \SKV@BeforePackageEnd{\code\}

 837
 \SKV@BeforeClassEnd{\code\}

 838
 \SKV@AfterPackageEnd{\code\}

 839
 \SKV@AfterClassEnd{\code\}

The first two of these hook to just before \AtEndOfPackage or \AtEndOfClass; the third and fourth hook to just after \AtEndOfPackage or \AtEndOfClass. They are all robust. These commands have been necessitated by some tasks in the skeyval package, but may be useful in some other contexts.

Macro

\SKV@AtDocumentStart{(code)}

\SKV@BeforeDocumentStart{(code)}

\SKV@AfterDocumentStart{(code)}

\SKV@AtDocumentEnd{(code)}

\SKV@BeforeLastPage{(code)}

 $SKV@AfterLastPage{(code)}$ 

\SKV@AfterDocumentEnd{(code)}

This is the robust version of the LATFX hook \AtBeginDocument. It can be used in expansion contexts without protection, but fragile arguments within it must be protected.

Macro

841 842

840

These provide two more document hooks. They are both robust. The command \SKV@BeforeDocumentStart differs from \AtBeginDocument in that the former is executed right at the end of the preamble, before the main auxiliary file (as written on the previous LATEX run) is read and prior to the execution of any AtBeginDocument code. It isn't possible to write to the auxiliary file at the point \SKV@BeforeDocumentStart is executed.

\SKV@AfterDocumentStart differs from \AtBeginDocument in the sense that the former is executed at the tag end of \begin\{document\}, after the execution of any \AtBeginDocument code. Commands whose scope are restricted to the document's preamble with \@onlypreamble or \SKV@onlypreamble are no longer committable when \SKV@AfterDocumentStart is being executed.

Macro

- 843 844
- 845
- 846

The last three of these are wrappers developed based on the atveryend package, which provides a consistent mechanism for \enddocument methods. The macro \SKV@AtDocumentEnd is the robust equivalent of \AtEndDocument. The macro \SKV@BeforeLastPage appends (code) after the \@enddocumenthook but before the last \clearpage, and thus before the last shipout. The command \SKV@AfterLastPage executes (code) after the last \clearpage invoked within \enddocument, i.e., after the last shipout but before the main auxiliary file is closed. This is, e.g., the right instance to record the last document page in the auxiliary file.

The command SKV@AfterDocumentEnd appends (code) to the very end of the document, after all of the end-of-document codes have been executed (i.e., after the main .aux file of the current pass has been read and all \AtEndDocument codes have been effected, except font and label/reference warnings).

# Inputting files

Macro

```
847
848
```

\InputFileOnce[{path}]{{file}}
\InputFileOnce\*[{path}]{{file}}

The unstarred variant of this command inputs  $\langle \texttt{file} \rangle$  on  $\langle \texttt{path} \rangle$  but only once in one LATEX pass. The argument  $\langle \texttt{path} \rangle$  is optional and its default value is the current/document's environment/directory. If  $\langle \texttt{file} \rangle$  had previously been read, a warning message is entered in the transcript log file (if the package option verbose is selected) and the input is aborted. If  $\langle \texttt{file} \rangle$  doesn't exist on  $\langle \texttt{path} \rangle$ , as many as desired opportunities are given to the user to type in the correct filename on the screen, or enter "no" to continue with the LATEX pass without inputting the file.

If the user wants to input  $\langle file \rangle$  more than once in one document, then he should use the starred (\*) variant of  $\InputFileOnce$ .

# 14 **References**

## 15 VERSION HISTORY

The following change history highlights significant changes that affect user utilities and interfaces; mutations of technical nature are not documented in this section. The numbers on the right-hand side of the following lists are section numbers; the star sign  $(\star)$  means the subject features in the package but is not reflected anywhere in this user guide.

# Version 0.1 [2010/01/01]

First public release under the name keyreader package	*
Introduced complementary native-boolean keys	4
Provided machinery for reading multiple keys of all kinds from just one command	7
Version 0.2 [2010/01/10]	
Fixed a bug and optimized the $\define@keylist loop$	7
Version 0.3 [2010/01/20]	
Introduced toggles and toggle-boolean keys	5
Version 0.4 [2010/02/01]	
Introduced complementary toggle-boolean keys	6

Inti	roduced the following macros	8
	\ifkeydefined, \ifkeyreserved, \ifkeysuspended	
Pro	vided the following facilities	8.2
	<pre>\newordkey, \newcmdkey, \newboolkey, \newchoicekey, \newtogkey, \define@biboolkeys, \newbiboolkeys, \define@bitogkeys, \newbitogkeys, \define@uniboolkeys, \newuniboolkeys, \define@unitogkeys, \newunitogkeys, \define@biuniboolkeys, \newbiuniboolkeys, \define@biunitogkeys, \newbiunitogkeys</pre>	
	wided mechanisms for disabling, localizing, reserving, unreserving, suspending, restoring, and removing keys	
Rec	lefined a few of xkeyval package's internal macros	
_		
Nor	malization of key-value lists before parsing	
	rmalization of key-value lists before parsing	
Inc	luded some developer macros	
Incl Ver		
Incl Ver Mo	<pre>huded some developer macros</pre>	ç
