

tikz-qtree: better trees with TikZ

David Chiang

Version 1 (22 Dec 2009)

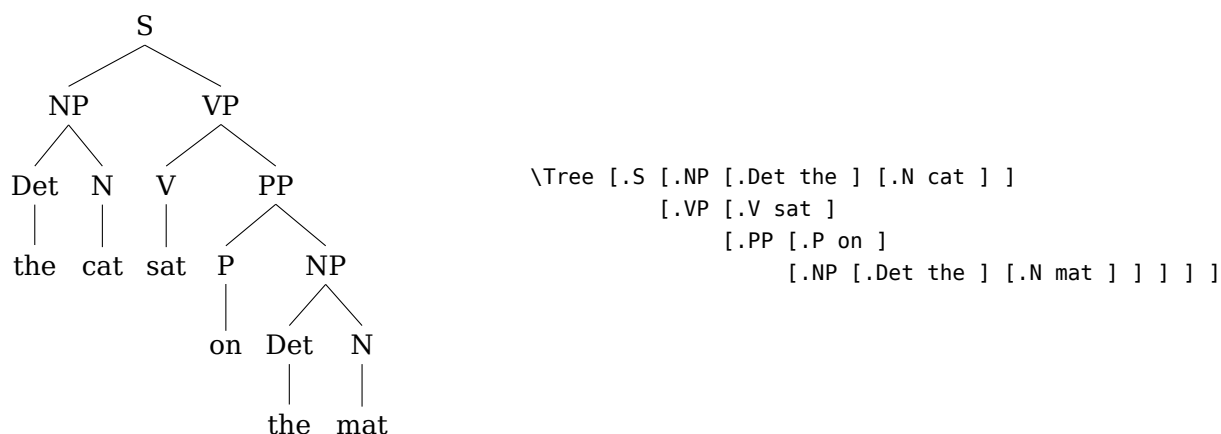

The `tikz-qtree` package provides a macro for drawing trees with TikZ¹ using the easy syntax of Alexis Dimitriadis' Qtree². It improves on TikZ's standard tree-drawing facility by laying out tree nodes without collisions; it improves on Qtree by adding lots of features from TikZ; and it improves on `pst-qtree` in being usable with pdfTeX and XeTeX.

1 Basics

To load the package in L^AT_EX:

```
\usepackage{tikz}
\usepackage{tikz-qtree}
```

The simplest usage is identical to Qtree:

Subtrees are delimited by square brackets. A subtree's root label is joined by a dot (.) to its opening bracket.³ As in Qtree, spaces are required after every (internal or leaf) node label.

`\Tree` works inside or outside a `tikzpicture` environment, but many of the features described below require the explicit `tikzpicture` environment.

¹<http://sourceforge.net/projects/pgf/>

²<http://www.ling.upenn.edu/advice/latex/qtrees/>

³You can also write the label after the closing bracket instead of the opening bracket, or both, or neither. Please see the Qtree documentation for details.

Options Some options for standard TikZ trees work for `\Tree` as well:

- `level distance`: vertical distance between the anchors of a parent and child
- `sibling distance`: horizontal distance between the boundaries of sister subtrees (not the anchors of their roots, as in standard TikZ trees). Note that TikZ nodes already have some horizontal space around them (`inner xsep`, by default `0.3333em`), so even `sibling distance=0pt` leaves some room.
- `grow=up` or `down`: trees grow up or down from their root. Other directions are not currently supported. The `grow'` option is the same, but children appear clockwise with respect to their parent instead of counterclockwise.

These are set either by writing `\tikzset{option=value}` or by writing `[option=value]` after a `\begin{tikzpicture}` or `\begin{scope}`.⁴ For example:

```

\begin{tikzpicture}
\tikzset{level distance=72pt}
\Tree [.NP [.Adj tall ] [.N tree ] ]
\end{tikzpicture}
%
\begin{tikzpicture}[grow'=up]
\Tree [.NP [.Adj upside-down ] [.N tree ] ]
\end{tikzpicture}

```

Styles TikZ lets you define *styles* which encapsulate multiple options:

```
\tikzset{small/.style={level distance=20pt,sibling distance=0pt}}
```

Then the option `small` causes the options in its definition to be used:

```

\begin{tikzpicture}[small]
\Tree [.NP [.Adj small ] [.N tree ] ]
\end{tikzpicture}
%
\begin{tikzpicture}
\Tree [.NP [.Adj normal ] [.N tree ] ]
\end{tikzpicture}

```

The following TikZ styles are automatically applied inside trees, providing a hook for you to change the appearance of particular kinds of tree parts:

- `every tree node` to every (internal and leaf) node (default: `anchor=base`)
- `every internal node` to every internal node
- `every leaf node` to every leaf node
- `edge from parent to every edge` (default: `draw`)

⁴Allowing options after `\Tree` would have made sense, but there would be no way to disambiguate the two uses of square brackets.

The options for nodes and edges are all handled by TikZ and are described in detail in the TikZ documentation. For example, if you have a font named `\ar` and want to set all the leaf labels in this font:

```

\begin{tikzpicture}
\tikzset{grow'=down}
\tikzset{every leaf node/.style={font=\ar}}
\Tree [.S [.NP القط ]
      [.VP [.V وجلس ]
            [.PP [.P على ] [.NP حصيرة ] ] ] ] ]
\end{tikzpicture}

```

If you want the edges to be darker:

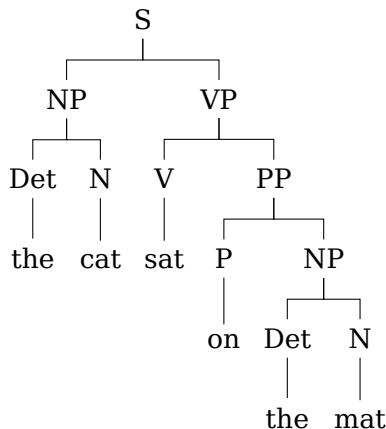

```

\tikzset{edge from parent/.style={draw,thick}}
\Tree [.S [.NP [.Det the ] [.N cat ] ]
      [.VP [.V sat ]
            [.PP [.P on ]
                  [.NP [.Det the ] [.N mat ] ] ] ] ] ]

```

The `draw` option is necessary, as by default they will not be drawn. As a more complex example, edges have an `edge from parent path` option which lets you change the shape of the edge. Its value is a TikZ path expressed in terms of `\tikzparentnode`, the parent node, and `\tikzchildnode`, the child node.

```

\tikzset{edge from parent/.style=
{draw,
edge from parent path={(\tikzparentnode.south)
-- +(0,-8pt)
-| (\tikzchildnode)}}}
\Tree [.S [.NP [.Det the ] [.N cat ] ]
      [.VP [.V sat ]
            [.PP [.P on ]
                  [.NP [.Det the ] [.N mat ] ] ] ] ] ]

```

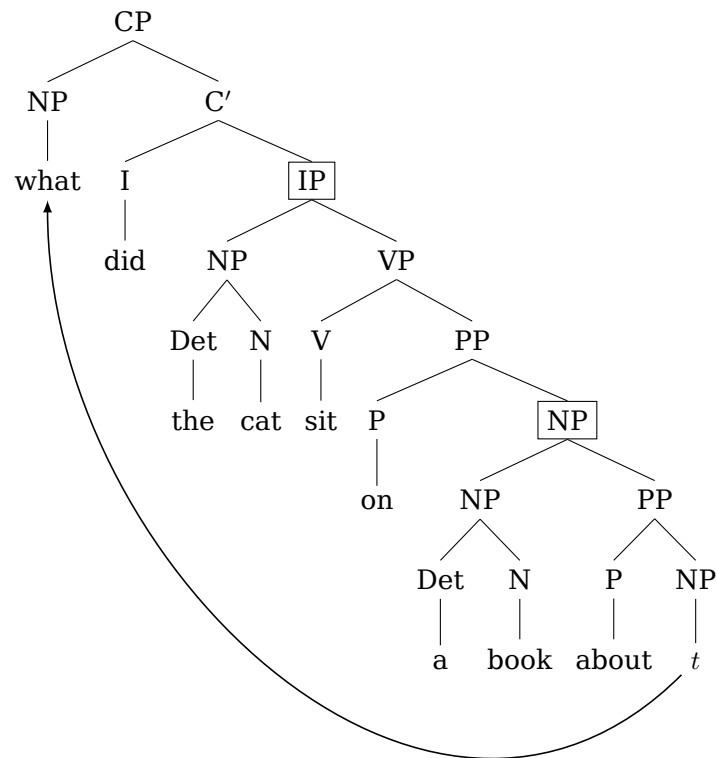

2 Embedding TikZ nodes

Inside a `\Tree`, in place of a node label, you can use a TikZ `\node` command.⁵

$$\backslash node [options] (name) \{label\};$$

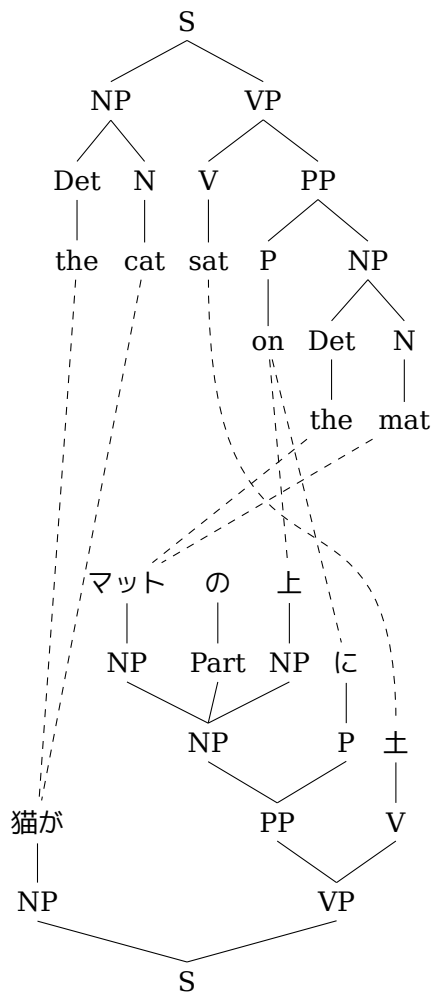

Don't forget the terminating semicolon. The `[options]`, which are optional, let you change the appearance of the node; for example, the `draw` option draws a border around the node. The `(name)`, which is also optional, can be used for drawing lines/arrows to/from the node.

```
\begin{tikzpicture}
\Tree [.\CP [.\NP \node{wh}{what}; ]
      [.\C$'$ [.\I did ]
            [.\node[draw]{IP};
              [.\NP [.\Det the ] [.\N cat ] ]
              [.\VP [.\V sit ]
                [.\PP [.\P on ]
                  [.\node[draw]{NP};
                    [.\NP [.\Det a ] [.\N book ] ]
                    [.\PP [.\P about ] [.\NP \node(t){t$}; ] ] ] ] ] ] ] ] ]
\draw[semithick,->] (t)..controls +(south west:5) and +(south:5) .. (wh);
\end{tikzpicture}
```

⁵\Tree specifically watches out for the token \node; do not use \path node or other equivalents.

Another example for machine translation people:

```
\begin{tikzpicture}
\Tree [.S [.NP [.Det \node(e1){the}; ]
        [.N \node(e2){cat}; ] ]
        [.VP [.V \node(e3){sat}; ]
        [.PP [.P \node(e4){on}; ]
        [.NP [.Det \node(e5){the}; ]
        [.N \node(e6){mat}; ] ] ] ]

\begin{scope}[yshift=-5in,grow'=up]
\tikzset{every leaf node/.style={font=\ja}}
\Tree [.S [.NP \node(j1){猫が}; ]
        [.VP [.PP [.NP [.NP \node(j2){マット}; ]
        [.Part \node(j3){の}; ]
        [.NP \node(j4){上}; ] ] ]
        [.P \node(j5){に}; ] ]
        [.V \node(j6){土}; ] ] ]

\end{scope}

\begin{scope}[dashed]
\draw (e1)--(j1);
\draw (e2)--(j1);
\draw (e3)..controls +(south:5) and +(north:4)..(j6);
\draw (e4)--(j4);
\draw (e4)--(j5);
\draw (e5)--(j2);
\draw (e6)--(j2);
\end{scope}

\end{tikzpicture}
```

3 Explicit edges

The edge from a parent to a child node is normally automatically drawn for you, but you can do it yourself with an `\edge` command *before* the corresponding child node. It is similar to the TikZ edge from parent command.⁶

```
\edge [options];
```

Again, don't forget the semicolon. The `[options]`, which are optional, let you change the appearance of the edge. You can also add an edge label:

```
\edge [options] node [options] {label};
```

Typically one will use the `auto` option for edge labels, which places the label to the side of the edge.

⁶Except that a TikZ edge from parent comes after the child node. I thought it was more logical to put it before.

```

\newcommand{\initial}[1]{\ensuremath{\alpha_{\textrm{\scriptsize #1}}}}
\newcommand{\auxiliary}[1]{\ensuremath{\beta_{\textrm{\scriptsize #1}}}}

\begin{tikzpicture}[level distance=36pt,sibling distance=12pt]
\Tree [. \initial{sat}
      \edge node[auto=right]{1}; \initial{cat}
      \edge[dashed] node[auto=left]{2};
      [.\auxiliary{on}
        \edge node[auto=left]{2}; \initial{mat} ] ]
\end{tikzpicture}

```

The fact that `auto=left` draws a label on the right and `auto=right` draws a label on the left makes sense if you think about the tree growing from the root to the leaves.

There is a predefined style that draws a “roof” over a node, like Qtree’s `\qroof`:

```

\begin{tikzpicture}[level distance=36pt]
\Tree [.S [.NP [.N this ] ]
      [.VP [.V is ]
        [.NP \edge[roof]; {a noun phrase
                           the complexity of which
                           is too great for me to parse} ] ] ]
\end{tikzpicture}

```
